ABSTRACT

The primary purpose of watermaster service is to distribute water among users in accordance with their established water rights. This is accomplished by apportioning available supplies in streams which have had water rights determinations./ Watermaster service was provided by the Department of Water Resources to 16 areas in Northern California during the 1967 watermaster season. They are: Ash Creek, Big Valley, Burney Creek, Butte Creek, Cow Creek, Digger Creek, Hat Creek, Indian Creek, Middle Fork Feather River, North Fork Cottonwood Creek, North Fork Pit River, Shackleford Creek, Shasta River, South Fork Pit River, Surprise Valley, and Susan River./ Essentially all of these areas experienced above-average water supplies during the 1967 irrigation season. The supply varied from average in some areas to the best year of record in others./ The bulletin is presented in two parts. Part I contains general information about water rights, water supply, and watermaster areas and duties. Part II contains specific information for each service area during the 1967 watermaster season, including available streamflow, methods and amounts of water distribution, and all other information pertinent to 1967 watermaster activities.

PART I - GENERAL INFORMATION

Distribution of water in watermaster service areas is a continuing statutory function of the Department of Water Resources as provided in Part 4 of Division 2 of the California Water Code.

The primary purpose of watermaster service is to distribute water in accordance with established water rights. This is accomplished by apportioning available supplies in streams which have had water right determinations.

A major benefit of watermaster service to water users and the State is that court litigation and physical violence, which in past years occurred quite frequently, are essentially eliminated. Under watermaster service each water right owner is assured that his rights are being protected without his having to take legal action against other users. Another important benefit results from increased use of available supplies through reduction of wasted water.

Because both the water right owners and the State receive benefits from watermaster service, the costs of performing the service are shared. The State general tax fund pays for one-half the cost of operating a service area. The water right owners in the service area pay the other one-half.

Determination of Water Rights

Water rights determinations for purposes of establishing a watermaster service area may be accomplished by "statutory" adjudication, "court" adjudication, permit or license to appropriate, or by agreement.

The California Water Code (Sections 2500-2900) contains procedures whereby water users on any stream may petition to have the State Water Resources Control Board, Division of Water Rights, make a legal determination of water rights on that stream. If the Board finds that such a determination is in the public interest, it proceeds with a Statutory Adjudication. This adjudication ultimately results in a court decree which defines all water

rights on the stream.

A similar but less extensive method of defining water rights involves a "court" adjudication procedure. When an action is brought before the Superior Court in the county in which there is a water rights dispute, the court has two methods available for its settlement. It may refer the action to the State Water Resources Control Board for a determination under authority contained in Sections 2000-2076 of the Water Code. Or, it may make an investigation of the facts and render a decision without referral to the Board.

These court adjudications determine only the water rights of parties named in the action and therefore do not necessarily define all water rights on the stream. Consequently, they sometimes precipitate serious conflicts between decreed water right owners and persons claiming rights for riparian lands which were not considered in the decree.

Almost all of the streams under state watermaster service have had their water rights defined by the courts under one of the above adjudication procedures. These adjudications (decrees) establish each owner's water rights as to allowable rate of diversion, season of use, point of diversion, and place of use. They also establish priorities whereby each owner's rights are shown in relation to the rights of all other decreed owners.

Under the priority system all first priority rights must be fully satisfied before water can be diverted to any lower priority rights (second, third, etc.). When a shortage occurs within any priority, the available water is proportioned among all owners of that priority.

Description of Watermaster Service Areas

A watermaster service area may be created either by petition from water users (Section 4050 of the Water Code) or by order of a Superior Court.

The first watermaster service areas were created in September 1929, while the most recent addition was made in June 1964. Prior to 1929, some watermaster service was provided in accordance with the Water Commission Act of 1913. There are now about 50 streams in Northern California which are under state watermaster service. These are combined into the 17 service

areas shown on Figure 1. Fifteen are in the Northern District and two are in the Sacramento District. The Seiad Creek service area is presently inactive.

The service areas are located primarily in the mountainous northeastern part of the State where the growing season varies between about 100 and 140 days. Meadow hay and alfalfa are the principal crops under irrigation, although a considerable amount of land is used exclusively for pasturing livestock. Most irrigation is accomplished by gravity systems, with water users diverting directly from the streams at one or more diversion points. However, pumped diversions and sprinkler irrigation systems are becoming popular in some areas.

Table 1 lists all watermaster service areas in Northern California, the date each was created, and the corresponding decrees and agreements under which each is operated.

Schematic drawings of the major stream systems within each service area are presented in Figures 2 through 17. These drawings show the relative location of major roads, stream gaging stations, diversion points, and water right allotments for each diversion. The diversion points shown in these figures correspond to those listed in the respective decrees which define the water rights.

Watermaster Responsibilities

To assure the proper distribution of water within his service area, each watermaster must ascertain the amount of water available and distribute it both by amount and priority in accordance with established water rights. To accomplish his purposes, the watermaster is provided authority both by the Water Code and by provisions of pertinent court decrees or voluntary agreements, to physically regulate the various streams in a service area. He is further authorized to supervise the design, construction, operation and maintenance of diversion dams, head-gates, and measuring devices.

Each watermaster supervises water distribution at approximately 100 to 200 diversions in one or more service areas. The frequency of visiting these diversion points substantially increases in years of short

* Explanation of type of Decree:

C Court adjudication (court makes determination from evidence submitted - no report of referee)

CR Court adjudication (referred to State Water Resources Control Board for investigation and report)

S Statutory adjudication (State Water Resources Control Board is petitioned by water users to make a determination of all water rights on a stream system)

** Decree entered by the superior court of this county.

water supply.

Permanent measurement and control devices, which the State requires at each owner's main point of diversion, are constructed by the water users under supervision of the watermaster. Installation of accurate, easily set, and lockable structures is a continuing objective of watermaster service, since once they are built, conflicts among water users almost always stop. Also, the watermaster's work is reduced greatly by good structures.

The watermaster is often called upon to make immediate field or on-the-spot interpretations of various court decrees, agreements, etc. Since most of these documents were written more than 30 years ago, many situations have developed that were not initially considered. Therefore, the watermaster must use sound, careful, and practical judgment in attempting to reach workable solutions to water disputes. To accomplish this he must possess a good understanding of California Water Law.

Water Supply

Water supply in the watermaster service areas is derived principally from unregulated runoff of small streams. Peak runoff, mostly snowmelt, occurs in the spring, with relatively small streamflow occurring in the summer and early fall. An additional supply from storage reservoirs or ground water is used in some areas to supplement natural streamflow.

In some service areas the water supply must be predicted in advance to determine the date watermastering will begin and to some extent, the manpower needed. The Department's Bulletin No. 120 series, "Water Conditions in California", is used to assist in these predictions.

Precipitation

The streamflow available for distribution is affected by total precipitation, amount of snowpack, air temperature, and the amount of precipitation received during the irrigation season. The latter is particularly important in the Upper Pit River-Surprise Valley areas, where about 25 to 30 percent of the annual precipitation occurs in

April, May and June. Spring storms, which are normally accompanied by cooler temperatures, materially affect both the supply and the demand for water.

Temperatures in the spring affect the demand for water and the manner in which snowmelt runoff occurs. A hot, dry spring depletes the water supply very early, even in years of normal snowpack. A cold, wet spring can extend the supply well into the irrigation season, but cold temperatures retard the growth of crops and are not necessarily desirable.

Data collected at representative snow courses showing the snowpack as of April 1, and May 1, 1967 are presented in Table 2. This information was obtained from the Department's Bulletin No. 120-67.

Table 3 presents information on precipitation at selected stations in the service areas. The seasonal precipitation gives an indication of the related water supply available for distribution and provides a basis for comparing the current year's supply with long time average supply.

Streamflow

The general water supply available for diversion within each watermaster area is determined from stream gaging stations placed at key locations in the main stream channels. The several major stations are installed and maintained either by the United States Geological Survey or by the Department of Water Resources as part of a Federal-State program for collection of year-round streamflow records. However, numerous other stream gaging stations are installed and operated by the watermaster during the irrigation season to provide supplemental information.

Additional gaging stations are often installed by the watermaster in selected diversion ditches to further assist him in proper distribution of the various water right allotments.

Table 4 presents runoff data at selected stream gaging stations in or near the service areas. Runoff data at stream gaging stations used by the watermasters are contained in tables following the description of each area. These data are used in conjunction with schedules showing total water rights to determine the adequacy or shortage of the water supply.

Essentially all watermaster service areas experienced above-average water supplies during the 1967 irrigation season. The degree varied from near average in some areas to the best year of record in others.

PART II - 1967 WATERMASTER SERVICE

This part of the report gives a general geographical description of each watermaster service area and the major sources of water supply therein. The usual methods of distribution and the actual distribution of the water supply of the 1967 season are discussed. Special occurrences in some areas are also mentioned.

Ash Creek Watermaster Service Area

The Ash Creek service area is located in Modoc and Lassen Counties near the town of Adin. There are 32 water right owners in this area with total allotments of 123.65 cubic feet per second.

The major sources of water supply for the service area are Ash Creek and three tributaries, Willow Creek, Rush Creek, and Butte Creek. Ash Creek rises in the eastern part of the service area and flows westerly through the town of Adin into Ash Creek Swamp and then into the Pit River. Rush Creek heads in the northeastern part of the service area and joins Ash Creek above the town of Adin. Willow Creek and Butte Creek originate in the southeastern part of the service area and join Ash Creek near the head of Ash Creek Swamp. Each of these streams is independently regulated.

Approximately 85 percent of the water rights in the service area are in Big Valley, west of the town of Adin. The remaining water rights are along the upstream tributaries and in Ash Valley. The portion of Big Valley served is approximately 10 miles long by 6 miles wide, extending from the town of Adin to the confluence of Ash Creek and the Pit River. The valley floor is at an elevation of approximately 4,200 feet.

A schematic drawing of each major stream system within the Ash Creek service area is presented as Figure 2, page 17.

Water Supply

The water supply for Ash and Rush Creeks is derived primarily

from snowmelt, since most of the watershed is between 5,000 and 6,000 feet in elevation. Willow Creek and Butte Creek receive a substantial portion of their water from springs. These creeks normally have sufficient water to satisfy demands until about June 1, after which the supply decreases rapidly. By the latter part of June, Ash Creek normally has receded to about 20 cubic feet per second, Rush Creek to about two cubic feet per second, Willow Creek to about five cubic feet per second, and Butte Creek to less than one cubic foot per second. The flow of these creeks then remains nearly constant for the remainder of the season.

The daily mean discharge of Ash Creek at Adin is presented in Table 5, page 19. This stream gaging station is located below a substantial number of the points of diversion; consequently, the table does not include all of the available supply of this creek.

No stream gaging stations were installed on Butte, Rush or Willow Creeks during the 1967 season.

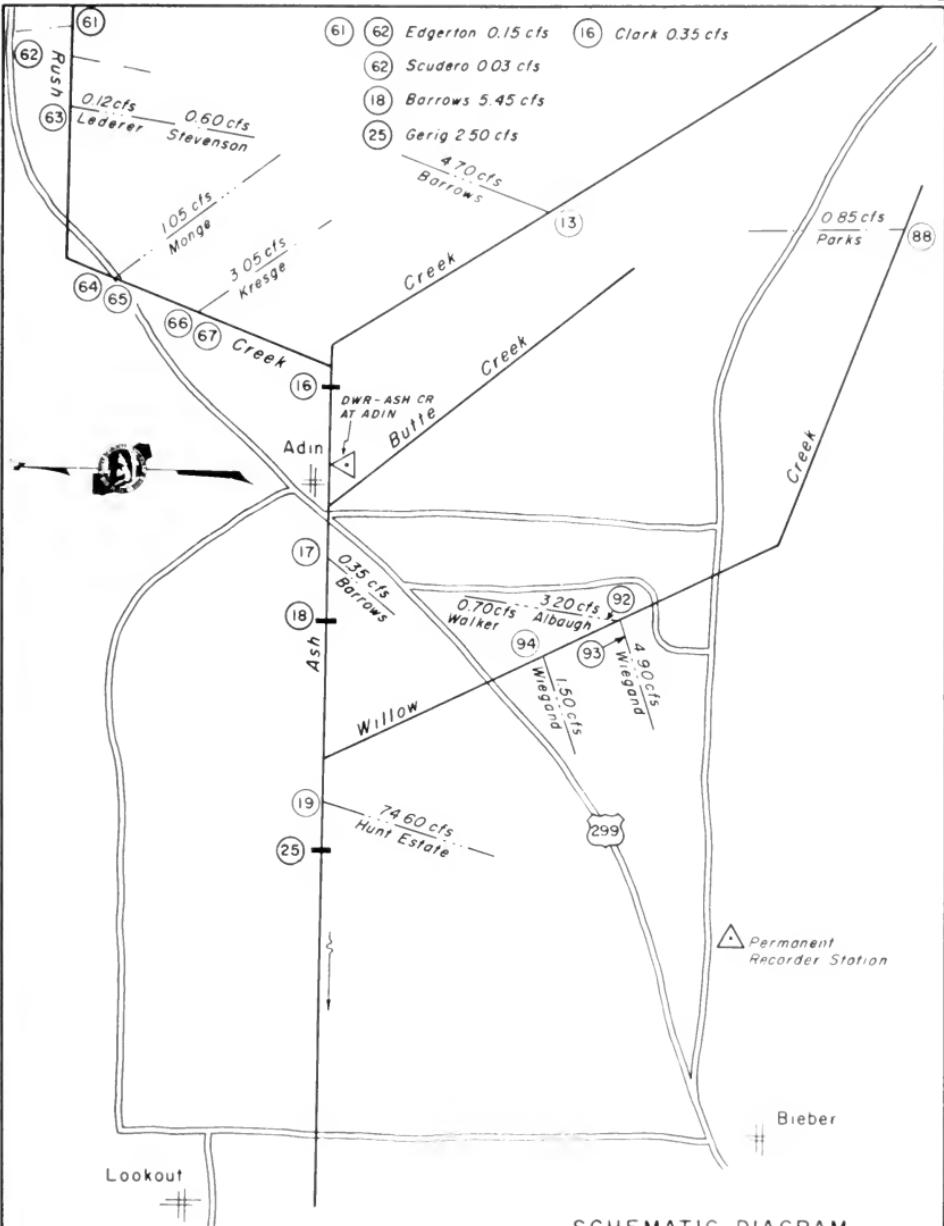

Method of Distribution

Irrigation diversions from Ash Creek and its tributaries are accomplished by small dams placed in the stream channels. Most of the users have several diversion ditches at these dams. These ditches convey the water to the fields where it is spread by means of small laterals. Some of the users employ a system of checks and borders; however, most of the land is irrigated by wild flooding. Return flow is captured by downstream ranches for reuse. In one case a rancher may recirculate his drain water before returning it to the creek for further use. In a few areas, pumps are used to divert the water into ditches or through sprinkler systems.

The Ash Creek decree (see Table 1) establishes the number of priority classes on the various stream systems within the Ash Creek service area as follows: Ash Creek - five; Willow Creek - four; Rush Creek - one; and Butte Creek - two.

Big Valley Watermaster Service Area

Big Valley service area is located in Modoc and Lassen Counties in the vicinity of the towns of Lookout and Bieber. There are 53 water right owners in the area with total allotments of 231.03 cubic feet per second.

The Pit River is the major source of water supply for the service area. The river enters the valley north of the town of Lookout and flows southerly through the western part of the valley and out its southern end. The major place of use is about 13 miles of valley floor along the Pit River at an approximate elevation of 4,200 feet.

A schematic drawing of the Big Valley stream system is presented as Figure 3, page 25.

Water Supply

The available water supply in the Pit River as it flows through Big Valley is ordinarily adequate to satisfy all demands until about June 1. The irrigation practices in Hot Springs Valley, located about 20 miles upstream from Big Valley, have a significant effect on the available water supply in Big Valley throughout the remainder of the irrigation season. Water users in Hot Springs Valley divert most of the flow in Pit River for two or three week periods. Natural flow available for use in Big Valley during these periods is often less than 20 cubic feet per second. Periodic releases from channel storage reservoirs in the lower end of the valley sometimes increase the flow to as much as 200 to 300 cubic feet per second for relatively short periods. Consequently, equitable water distribution in Big Valley is very difficult to attain.

Roberts Reservoir, located on a minor tributary of the Pit River at the upper end of Big Valley above Lookout, serves as a supplemental source of water to those users in the area who are members of the Big Valley Mutual Water Company. Water from this reservoir is

released into the Pit River and distributed to members of the water company along with the natural flow to which they are entitled.

Records of two stream gaging stations in the Big Valley service area are presented in Tables 6 and 7, pages 27 and 28.

Method of Distribution

Most water users in the Big Valley service area irrigate on a rotation schedule by either wild flooding or by checks and borders. Large flashboard dams placed in the channel make it possible to use the large heads of water characteristic of the supply in the area. In addition, some pumps are used for diversion, both in ditches and directly into sprinkler systems. The ranches which irrigate by wild flooding must use large heads of water in order to cover unleveled or high ground. Much of the runoff is recaptured for use by downstream lands, resulting in a relatively high irrigation efficiency for the valley.

The Big Valley decree (see Table 1) provides for the distribution of water from Pit River in four priority classes.

1967 Distribution

Watermaster service began May 1 in the Big Valley service area and continued until September 30. Virgil D. Buechler, Water Resources Technician II, was watermaster during this period.

A near record snowpack, combined with continuing storms through April and May, provided a plentiful water supply. Many long-time residents had hay crops of record yield.

During May and early June, flows in the Pit River in Big Valley averaged more than 500 cubic feet per second. This greatly exceeded all demands and prevented installation of several flashboard dams. By June 5 the flow had decreased enough to allow the owners of the Bieber and Ricketts dams to place them in operation. The river is divided into two channels in this reach thus reducing the flows each dam must pass. On July 7 the flow had receded to about 200 cubic feet per second which allowed installation of the Lookout and Gerig dams.

By August 1, the first hay cutting in the valley was nearly completed and most ranchers were beginning to resume irrigation. However, large diversions by upstream users in Hot Springs Valley reduced the Pit River flow reaching Big Valley to 5 cubic feet per second. This necessitated the use of a rotation program. The watermaster allowed an irrigation allotment of 15 acre-feet for each cubic foot per second of second priority water right. Most of the water was required to fill the many channels and sloughs which had dried up during haying. Consequently, this period produced an insufficient irrigation.

On September 9 a similar and more successful irrigation rotation was completed. Releases from Hot Springs Valley then increased substantially, providing enough flow to allow two complete rotations of second priority allotments (four priorities) by the end of the irrigation season.

From August 2 to August 31 water was released from Roberts Reservoir for use by shareholders as follows:

Burney Creek Watermaster Service Area

The Burney Creek service area is located in Shasta County near the town of Burney. There are 10 water right owners in the area with total allotments of 33.09 cubic feet per second. The source of water supply for this service area is Burney Creek, which enters the southern part of the service area and flows through Burney in a northerly direction to the Pit River. The portion of the valley served by this stream is approximately 11 miles long and two miles wide, and extends both north and south of Burney. The service area is at approximately 3,200 feet elevation.

A schematic drawing of the Burney Creek stream system is presented as Figure 4, page 31.

Water Supply

The water supply for Burney Creek comes from springs and snowmelt. Most of the watershed lies between the elevations of 4,000 and 7,500 feet on the northeast slopes of Clover Mountain and the west slopes of Burney Mountain. The creek normally has sufficient water to supply all demands until about the middle of June. The supply then gradually decreases until the end of July. For the remainder of the irrigation season, runoff from perennial springs keeps the flow nearly constant at approximately 40 percent of allotments.

The daily mean discharge of Burney Creek near Burney is presented in Table 8, page 33. The stream gaging station on Burney Creek is located below four points of diversion; consequently, the records do not show all of the available water supply of the creek.

Method of Distribution

The Burney Creek decree (see Table 1) sets forth a rotation schedule of distribution. The water users, however, have found it more beneficial to irrigate on a continuous-flow basis (one priority class

plus surplus allotments), which is now normal practice. The water allotted to the Greer-Cornaz Ditch is distributed in accordance with a supplemental court decree.

Water is diverted from Burney Creek, in most cases by means of low diversion dams, into ditches which convey it to the place of use. Lateral ditches are then used to irrigate the land. Scott Lumber Company uses a pump and pipeline to divert its allotment for industrial use.

1967 Distribution

Watermaster service began May 1 in the Burney Creek service area and continued until September 30. Virgil D. Buechler, Water Resources Technician II, was watermaster during this period.

All allotments were distributed on a continuous flow basis. This practice, rather than that of rotation called for in the decree, has been used for many years under agreement of the water right owners. The available water supply for the 1967 irrigation season was above average due to above normal precipitation during the late winter and spring months.

Surplus flow was available to all users until August 10, at which time all irrigation diversions were regulated to 100 percent of first priority allotments. Throughout the remainder of the season the flow remained near this level.

Butte Creek Watermaster Service Area

The Butte Creek service area is located in Butte County near the City of Chico. There are 35 water right owners in the area with total allotments of 219.71 cubic feet per second. Butte Creek is the major source of water supply. The area served by this stream extends from about four miles east of Chico to the diversion of the Great Western Canal, about 11 miles south. It contains about 20,000 acres of valley floor lands at an average elevation of 150 feet.

A schematic drawing of the Butte Creek stream system is presented as Figure 5, page 39.

Water Supply

Butte Creek rises on the west slope of the Sierra Nevada Mountains in the northeasterly portion of Butte County, between Humbug and Humboldt Passes, at elevations of 5,000 to 6,000 feet.

Snowmelt normally produces sustained high flows until about the end of June, after which perennial springs at the headwaters continue to produce flows of more than 40 cubic feet per second. Additional water is imported from the West Branch Feather River by means of the Hendricks (Toad Town) Canal through DeSabla Reservoir and Powerhouse into Butte Creek. This imported water is rediverted at Parrott Dam to the Parrott Ditch.

Records of the daily mean discharge at several stream gaging stations in the Butte Creek service area are presented in Tables 9 through 11, pages 41 through 43.

Methods of Distribution

Water is diverted from Butte Creek by pumping and by gravity diversions. Parrott Investment Company, M & T Incorporated, Dayton Mutual Water Company, Durham Mutual Water Company divert relatively large amounts of water into several ditches leading to their individual

distribution systems. Various methods of irrigation are in general practice. These include contour checks, strip or border checks, basin checks, furrows, wild flooding, and sprinklers. The use of sprinklers has increased in popularity within the past few years, especially for use on orchards.

Water diverted from the West Branch Feather River through the Hendricks Canal and Desabla Powerhouse in Butte Creek has, in the past, caused wide fluctuation in the Butte Creek flow. In accordance with "Memorandum and Order" entered May 10, 1949, by the Superior Court of Butte County, water users below Parrott Dam (where the imported water is rediverted) must be provided their natural flow allotments at all times without undue fluctuation caused by intermittent presence of imported water. For the past several years PG&E has maintained reasonably steady releases which have greatly simplified this rediversion problem.

The Butte Creek decree (see Table 1) established three priority classes for summer distribution purposes and, in addition, defined two surplus flow allotments.

1967 Distribution

Watermaster service began June 1 in the Butte Creek service area and continued until September 30. Ross P. Rogers, Water Resources Engineering Associate, was watermaster during this period.

The available water supply for the 1967 irrigation season was outstanding. More low priority allotments were served for a longer period than in any other irrigation season since watermaster service began in the area in 1943.

Flow past the Gorrill Land Company's diversion dam, which is usually cut off in late May or early June, continued until mid-July. Deliveries to the White Ranch, the only water right owner in the service area below Gorrill Dam, were then made through Hamlin Slough for the remainder of the season.

Enough water was available to satisfy all demands in the surplus class until the third week in July, as some water users in

this class did not request their full entitlement. Near the end of July the flow had decreased, but was still adequate to serve the three highest priorities in the surplus class (six priorities in this class from July through September).

During the first week in August the flow in Butte Creek dropped rapidly. On August 7 there was enough water for about 50 percent of the first priority surplus class. Throughout the remainder of the month the flow decreased slightly, but still provided some water for this priority.

For a few days near the end of August and in early September the flow dropped below the surplus stage into the third and second priority allotments (three priorities) of the "regular summer schedule".

During the second week in September and continuing throughout the season the available water supply began to increase due to the gradual reduction of irrigation by many water right owners.

Special Occurrences

Several applications to appropriate surplus water during the spring months are presently under consideration by the State Water Resources Control Board, Division of Water Rights. If these applications are approved, the length of watermaster service to the area will probably be extended. Work would probably begin in late April or early May.

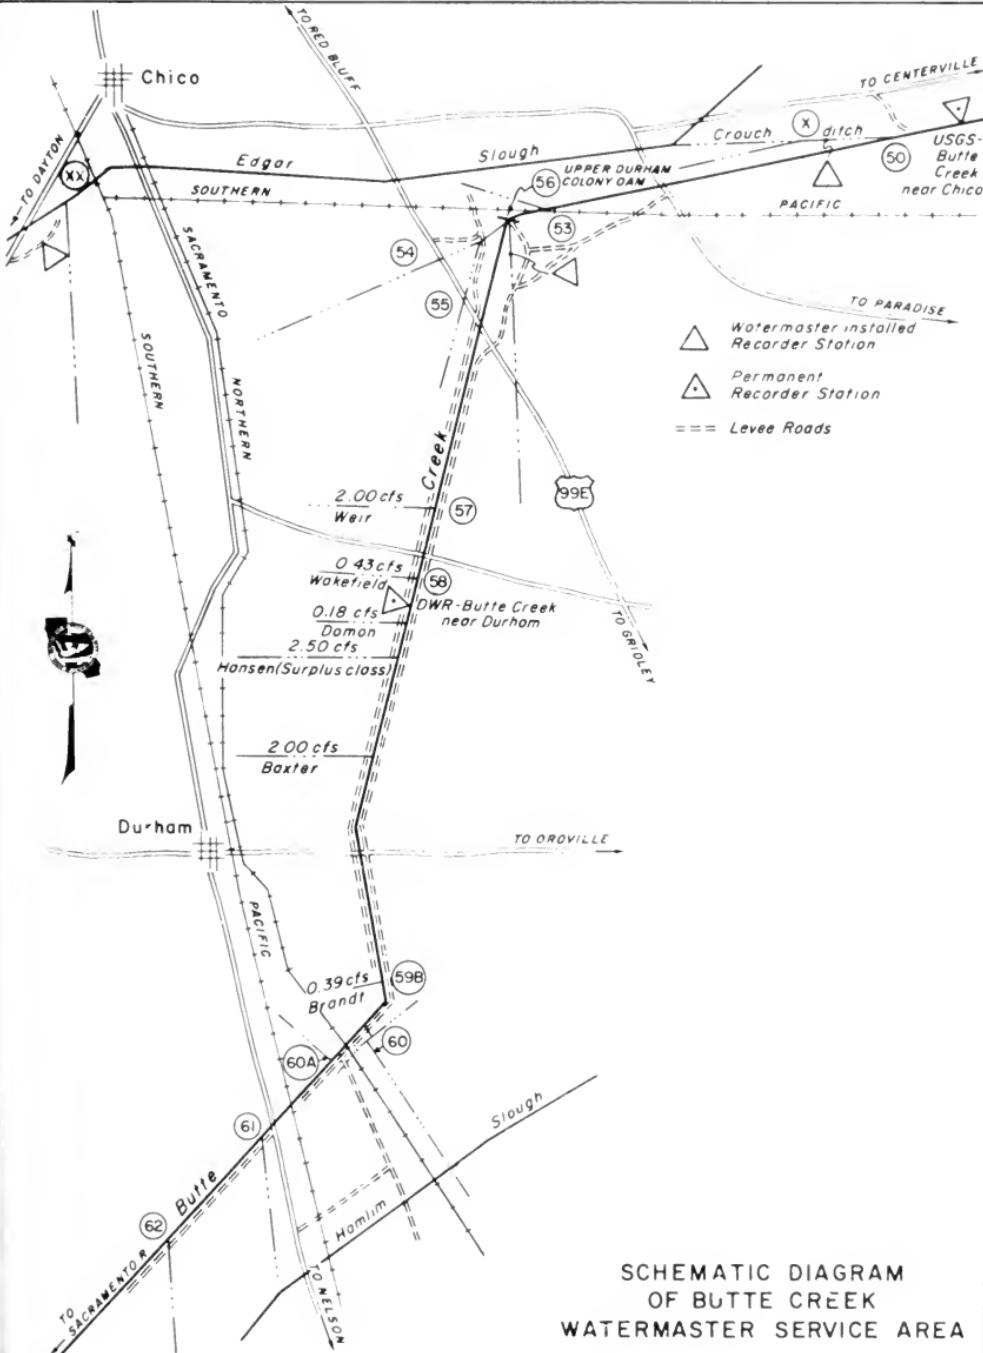

Several measuring devices are planned for construction prior to the beginning of the 1968 irrigation season. Those needed most are: a Parshall flume in the Gorrill Land Company's diversion ditch; a Parshall flume and two rectangular weirs to be placed in existing concrete structures in the Newhall Land and Farming Company's diversion system; a rectangular weir and concrete structure in Hamlin Slough; and repair of an existing Parshall flume in the Camenzind Brothers diversion ditch.

Cow Creek Watermaster Service Area

The Cow Creek service area is located in Shasta County in the foothills east of Redding. There are 88 water right owners in the area with total allotments of 56,366 cubic feet per second. The major streams in this area are: North Cow Creek (commonly called Little Cow Creek), Cedar Creek (which is tributary to North Cow), Oak Run Creek, and Clover Creek. These creeks, which are all tributaries of Cow Creek, flow in a westerly or southwesterly direction through narrow valleys joining Cow Creek near the town of Palo Cedro. The service area is located in the narrow valleys along the several creeks and consists of small parcels separated by brush-covered hills. The entire area is about 25 miles long by 10 miles wide and varies in elevation between about 500 and 2,000 feet.

A schematic drawing of each major stream system in the Cow Creek service area is presented as Figures 6 through 6c, pages 49 through 55.

Water Supply

Water supply for this service area is derived mostly from springs and seepage with some early snowmelt runoff. The watershed consists primarily of low brush hills which do not accumulate a heavy snowpack. Relatively large amounts of precipitation during the winter normally produce substantial springs and seepage that flow throughout the irrigation season.

Cedar Creek flow is usually sufficient to supply all allotments until about July 15, after which time it steadily decreases throughout the remainder of the season.

The flow of North Cow Creek is generally adequate to supply all allotments. In dry years it is necessary to reduce allotments during the latter part of the summer.

The flow of Oak Run Creek is augmented by a first priority allotment of five cubic feet per second of imported water from the North Cow

Creek watershed. The combined flow is generally adequate to supply all allotments throughout the season.

Clover Creek generally supplies enough water to meet all allotments throughout the season.

There were no stream gaging stations operated in the Cow Creek service area during 1967. Numerous stations were maintained in various diversion ditches.

Methods of Distribution

Water in the Cow Creek service area is used for domestic and stockwatering purposes and for irrigation of meadow hay, alfalfa, small orchards, and vegetable gardens. The alfalfa and hay lands are irrigated primarily by wild flooding, although some sprinklers are used. Furrows are used for irrigating gardens, and basins or checks and sprinklers are used for orchards. Much of the water applied is lost by surface runoff or by deep percolation, some of which returns to the creeks and thereby becomes available for redirection downstream.

Only one priority allotment was provided in each of the Cow Creek service area decrees (see Table 1) except that the Oak Run Creek decree also contains a surplus allotment.

1967 Distribution

Watermaster service began June 15 in the Cow Creek service area and continued until September 30. Ross P. Rogers, Water Resources Engineering Associate, was watermaster during this period.

The available water supply for the Cow Creek service area was outstanding. An unusually late spring, combined with considerable rainfall and an excellent snowpack at higher elevations, produced the high sustained flows. Almost all water right owners received adequate water throughout the irrigation season.

Despite above average temperatures for extended periods, with their attendant high evaporation and ditch losses, a very successful irrigation season was enjoyed by most users.

Cedar Creek. Cedar Creek consistently has the lowest water

supply to water rights ratio in the Cow Creek service area. Even in years of adequate supply on nearby streams, the allotments on Cedar Creek are usually rationed severely.

However, because several water right owners did not use their full entitlements during the 1967 season all other users received an adequate supply throughout the summer.

North Cow Creek. The water supply in North Cow Creek was one of the best on record. Above normal spring rainfall contributed heavily to replenishment of the underground reservoirs which provide the major source of supply to the headwaters of the creek in the summer.

Even though most water right owners were diverting considerably more than their allotments, unused surpluses existed at the lower end of the creek until late July. Throughout August, historically a critical month, all users who could beneficially use surplus water were allowed to divert up to 200 percent of their allotments.

The flow in the creek decreased slightly in early September, requiring all diversions to be limited to about 125 percent of allotments for most of the month.

Oak Run Creek. The available water supply in Oak Run Creek was sufficient to supply all demands throughout the season. Several water right owners diverted amounts in excess of their allotments.

Water was available for irrigation of riparian lands downstream from the adjudicated area throughout the summer. This is an unusual occurrence.

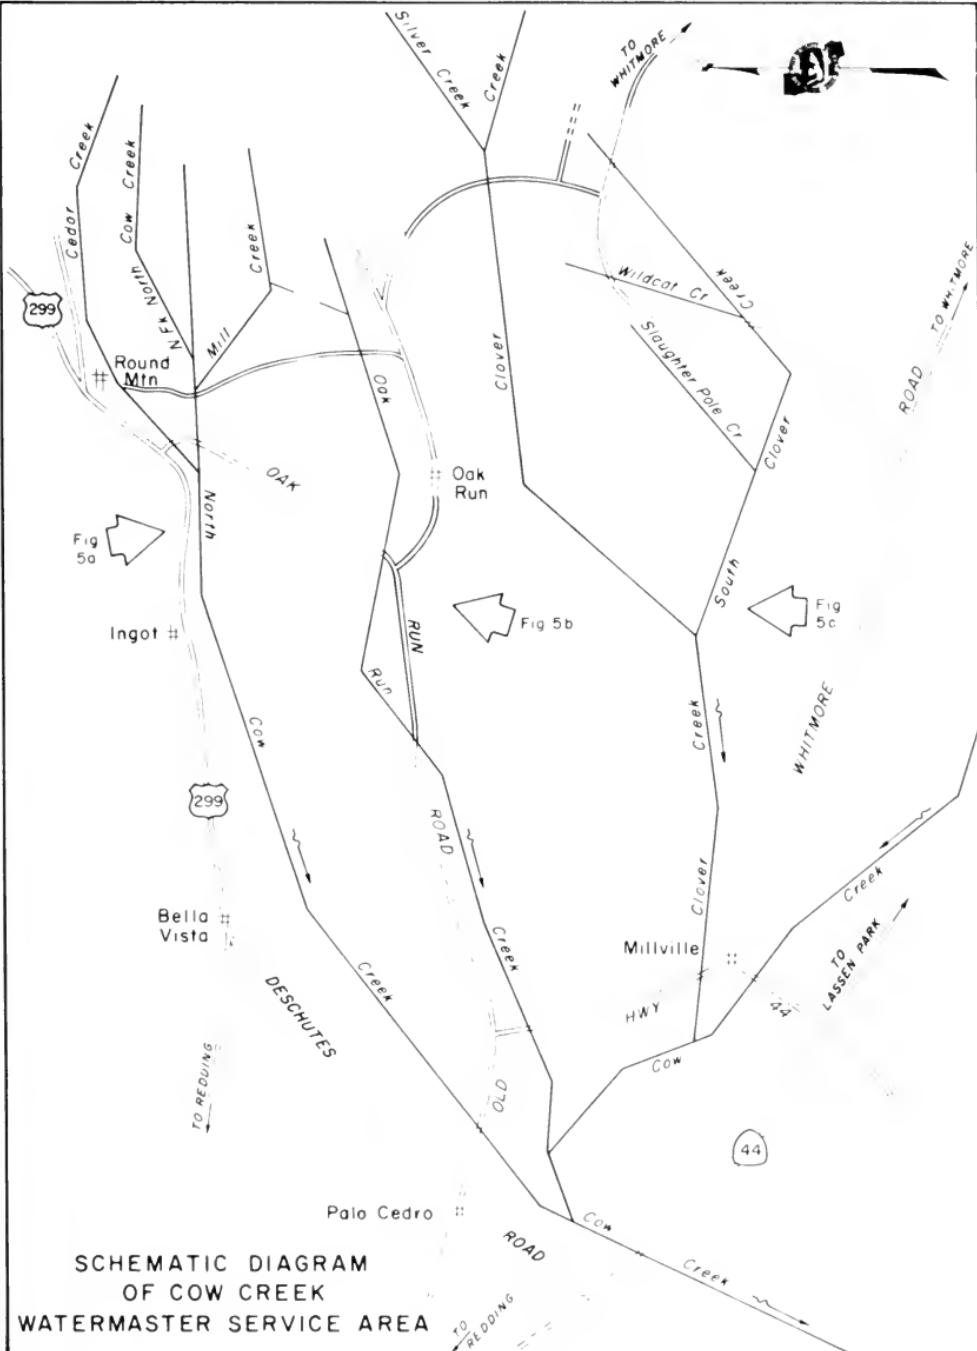

Clover Creek. The available water supply in Clover Creek was sufficient to supply all demands. Surplus water was available throughout the season.

Several water right owners diverted as much as 125 percent of their allotments during the normally critical months of August and September.

Special Occurrences

A two-foot concrete Parshall flume and a concrete control and spill-back structure with a screw-type metal headgate were constructed in the Worley Ditch on Clover Creek. Planned for construction prior to

the 1968 irrigation season are: Upper North Cow Creek - two concrete control structures with metal headgates and a concrete automatic division box; Lower Cow Creek - a concrete Parshall flume; Oak Run Creek - a wooden automatic division box and improvements to several existing division boxes; Clover Creek - a concrete automatic division box.

Digger Creek Watermaster Service Area

The Digger Creek service area is located in portions of south-eastern Shasta County and northeastern Tehama County. There are 33 water right owners in the area with total allotments of 23,225 cubic feet per second.

Digger Creek forms a portion of the boundary line between Shasta County on the north and Tehama County on the south. It drains an area of approximately 45 square miles on the western slopes of mountains situated immediately west of Lassen National Park. The creek flows in a westerly direction through the town of Manton to its confluence with North Fork Battle Creek. Manton, the only community in the area, is located approximately 40 miles northeast of Red Bluff.

A schematic drawing of the Digger Creek stream system is presented as Figure 7, page 61.

Water Supply

Precipitation, occurring principally in the winter months, is typical of Northern California foothill areas. Snowmelt contributes to the early runoff but the summer streamflow is primarily from springs. In average runoff years there is sufficient flow in Digger Creek, with careful regulation, to satisfy all decreed allotments throughout the entire irrigation season. However, serious deficiencies occur in dry years.

The estimated daily mean discharge of Digger Creek below South Fork Branch is presented in Table 13, page 63.

Method of Distribution

There are four court decrees (see Table 1) on Digger Creek. These decrees, in effect, have divided the water rights on the creek into two groups: the upper users and the lower users. The three upper users irrigate lands adjoining the stream, so that all water not consumptively used returns to Digger Creek. The lower users are located within

a three-mile reach of the stream and within a five-square-mile area. Very little runoff from the lower users returns to the creek.

The three upper users' water rights are absolute and not correlative to the lower users; therefore, allotments are not cut proportionally as Digger Creek flows decrease. The lower users, whose water rights total 12 cubic feet per second, have their allotments cut proportionally as the flow decreases. In effect, the upper users have first priority allotments and the lower users have second priority allotments.

Irrigation is done principally by wild flooding, although border checks and sprinklers are used on a few fields. Small diversion dams are placed in the stream channel to divert water into ditches for conveyance to the fields.

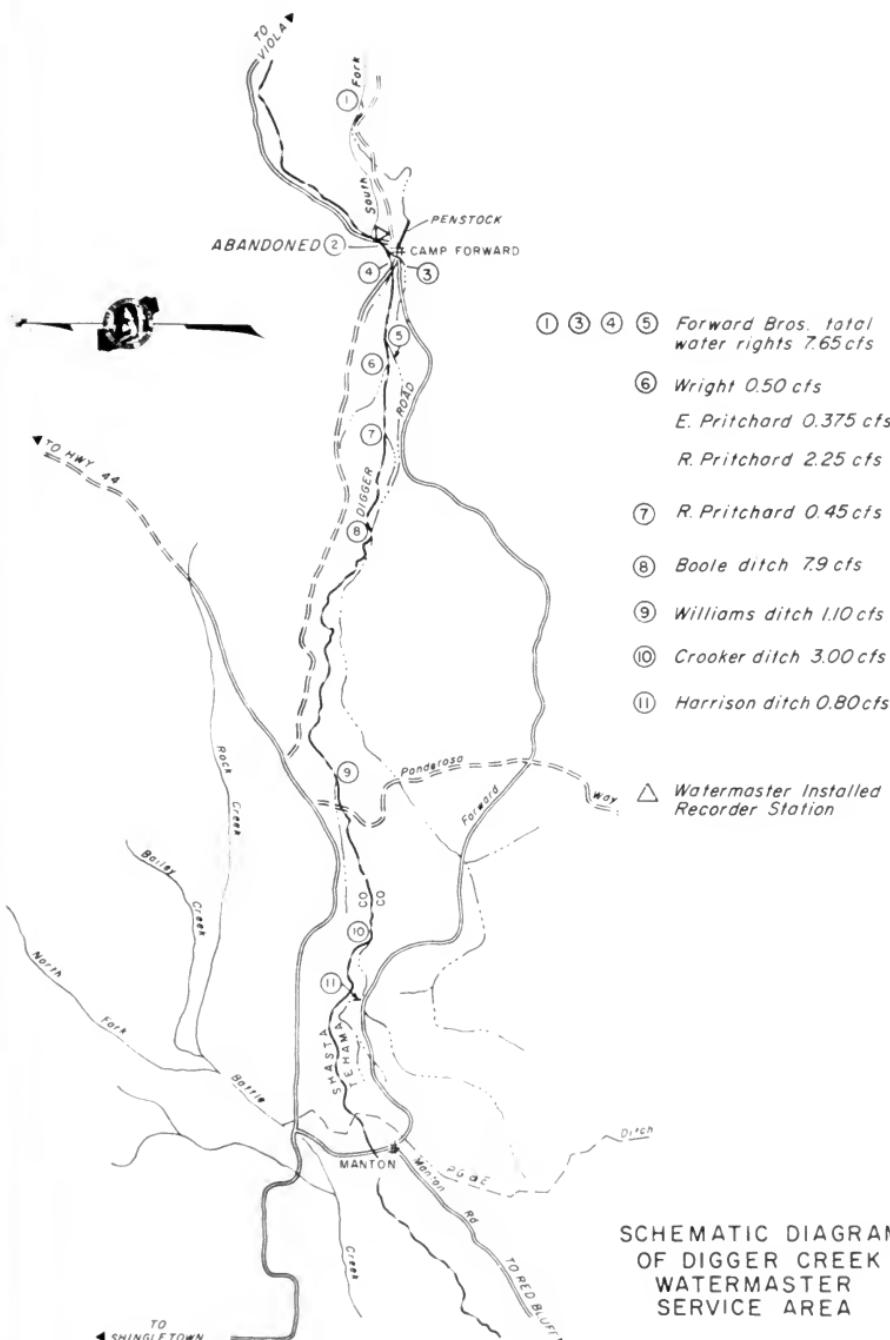

1967 Distribution

Watermaster service began July 1 in the Digger Creek service area and continued until September 30. Ross P. Rogers, Water Resources Engineering Associate, was watermaster during this period.

The available water supply in Digger Creek was outstanding. During the usually critical months of August and September all water users received 100 percent or more of their allotments. In addition, surplus quantities ranging from 10 to 25 percent of the total adjudicated water rights flowed unused from the service area.

Special Occurrences

The Harrison Ditch water rights were again diverted into the Crooker Ditch for about a quarter-mile and then rediverted to the Harrison Ditch. An agreement between the water right owners in both ditches finalizing this arrangement is expected to be signed shortly. An automatic concrete division box will then be constructed at the point of redirection of the Harrison Ditch water.

Hat Creek Watermaster Service Area

The Hat Creek service area is located in the eastern part of Shasta County north of Lassen Volcanic National Park. There are 44 water right owners in the area with total allotments of 135,035 cubic feet per second. Hat Creek, which flows in a northerly direction through the area, is the only source of water supply in the service area. The place of use is Hat Creek Valley, which is approximately 20 miles long and two miles wide. Commencing at a point about three miles south of the town of Old Station, the valley extends northward to the confluence of Rising River and Hat Creek. The irrigable lands, which consist primarily of volcanic ash, are interlaced with large outcroppings of volcanic rock.

Schematic drawings for both the upper and lower users' diversion systems from Hat Creek are presented as Figures 6 through 6b, pages 67 through 71.

Water Supply

The water supply of Hat Creek is derived from snowmelt runoff on Mount Lassen and from large springs. Snowmelt normally creates a high flow during May and June; however, the substantial portion of supply during the summer months comes from large springs which decrease only slightly in output. Only after a series of dry years does the flow of these springs fall much below 75 percent of the total allotments.

A record of the daily mean discharge of Hat Creek near the town of Hat Creek is presented in Table 14, page 13.

Method of Distribution

The Hat Creek decree (see Table 1) divides the water rights on Hat Creek into two groups (upper users and lower users) who use the water on a 10-day rotation schedule, with one priority class for each group as the basis for distribution. This requires a complete re-regulation of all diversion every 10 days, alternating an irrigation supply to one group

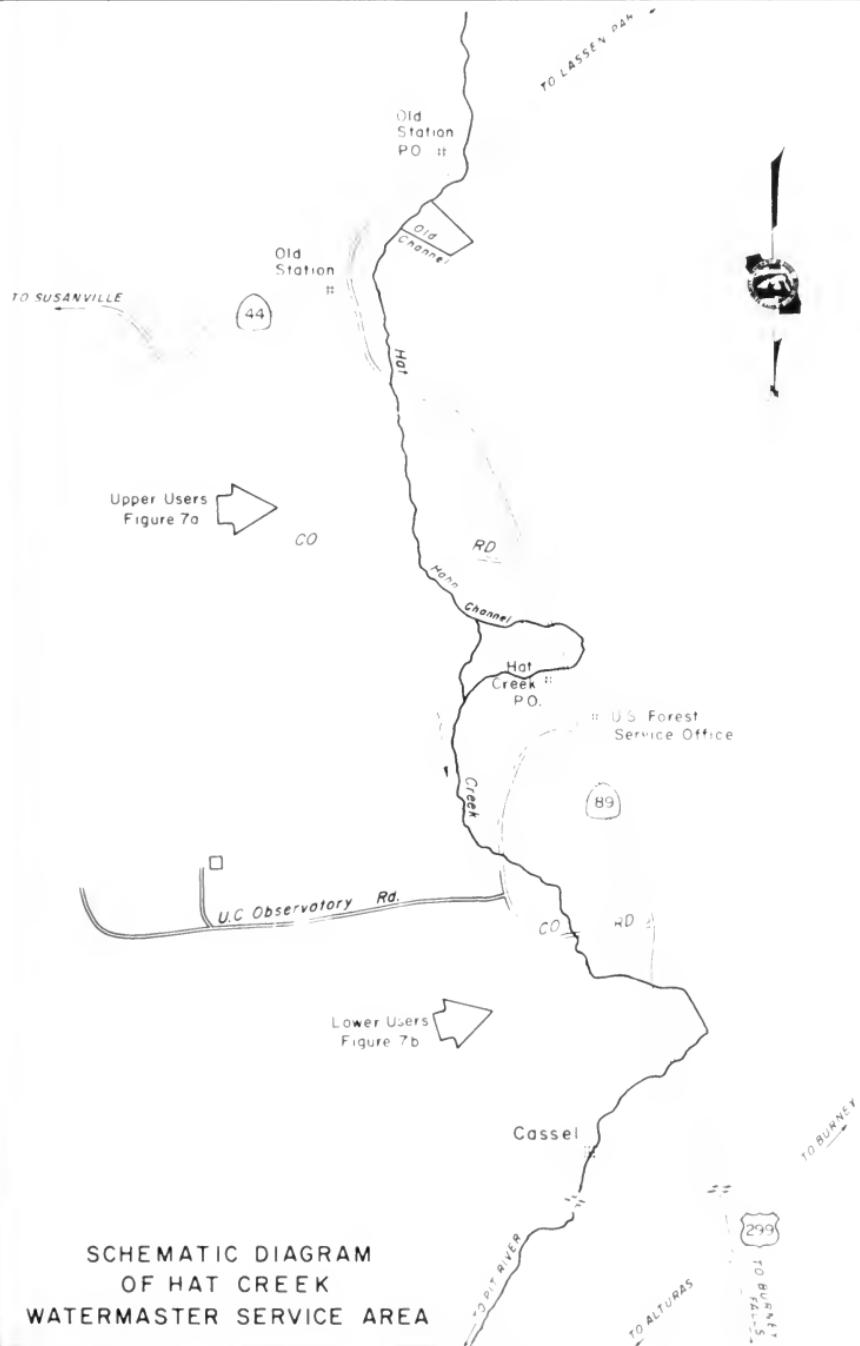

and a minimum flow (stockwater) to the other group.

Most irrigation in the area is accomplished by wild flooding. Large heads of water are used to cover the land rapidly, thereby preventing excessive loss from percolation in the extremely porous soil. Diversion dams constructed across the creek serve to divert water into large ditches. The fields, many of which have checks and borders, are then flooded from the main diversion ditch or from laterals. A few domestic rights are met by pumping directly from Hat Creek.

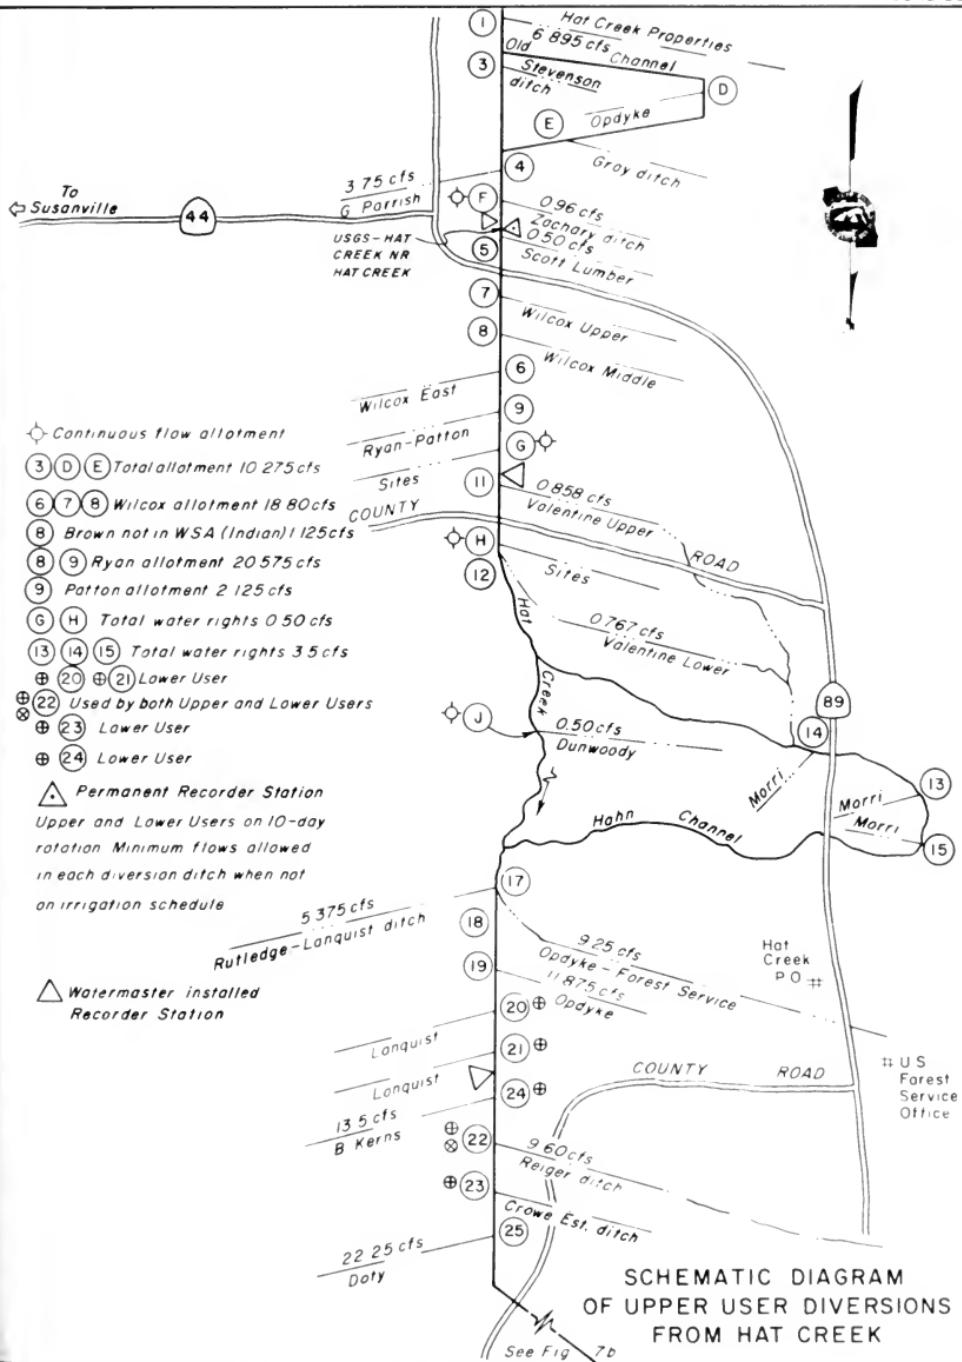

1967 Distribution

Watermaster service began May 1 in the Hat Creek service area and continued until September 30. Virgil D. Buechler, Water Resources Technician II, was watermaster during this period.

The available water supply in Hat Creek was far above average through July. Therefore, the usual 10-day rotation schedule was not put into effect until August 1. The flow then gradually decreased until by August 19, it was necessary to regulate the lower users to 80 percent of their first priority allotments. The flow then remained essentially constant for the remainder of the season.

Indian Creek Watermaster Service Area

The Indian Creek service area is located in the north central part of Plumas County in the vicinity of the town of Greenville. There are 43 water right owners in the service area with total allotments of 97.015 cubic feet per second. The major sources of supply in the service area are Indian Creek and two major tributaries, Wolf Creek and Lights Creek. Indian Creek and its minor tributaries rises in the mountains east of the service area. It then flows through Gennessee Valley and through Indian Valley past the towns of Taylorsville and Crescent Mills to its confluence with the North Fork Feather River. Indian Creek is joined from the north by Lights Creek and Wolf Creek in the northwest part of the valley. The major place of use is in Indian Valley, which is about four miles long and two and one-half miles wide. The average elevation is about 3,500 feet.

A schematic drawing of each major stream system within the Indian Creek service area is presented as Figures 9 through 9c, pages 77 through 83.

Water Supply

The water supply in the Indian Creek service area is derived primarily from snowmelt runoff with springs and seepage maintaining some late summer flow. The flow of Wolf Creek is normally sufficient to supply all allotments until June 1, while Indian and Lights Creeks, with the exception of some tributaries, have sufficient flow to supply all allotments until July 1. After these dates, the flow steadily decreases throughout the season until by the end of August only a small portion of allotments is available.

A record of the daily mean discharge of Indian Creek near Taylorsville is presented in Table 15, page 35.

Method of Distribution

The basic method of irrigation in Indian Valley is wild flooding.

Small diversion dams are placed in the stream channels to divert the water into distribution ditches for conveyance to the fields. Small check dams, located throughout the fields in swales, help to spread the water over the ground. There is a limited amount of check and border irrigation in the valley. A few sprinkling systems are also in use.

The Indian Creek decree (see Table 1) establishes three priority classes for each of the major stream systems within the Indian Creek service area.

1967 Distribution

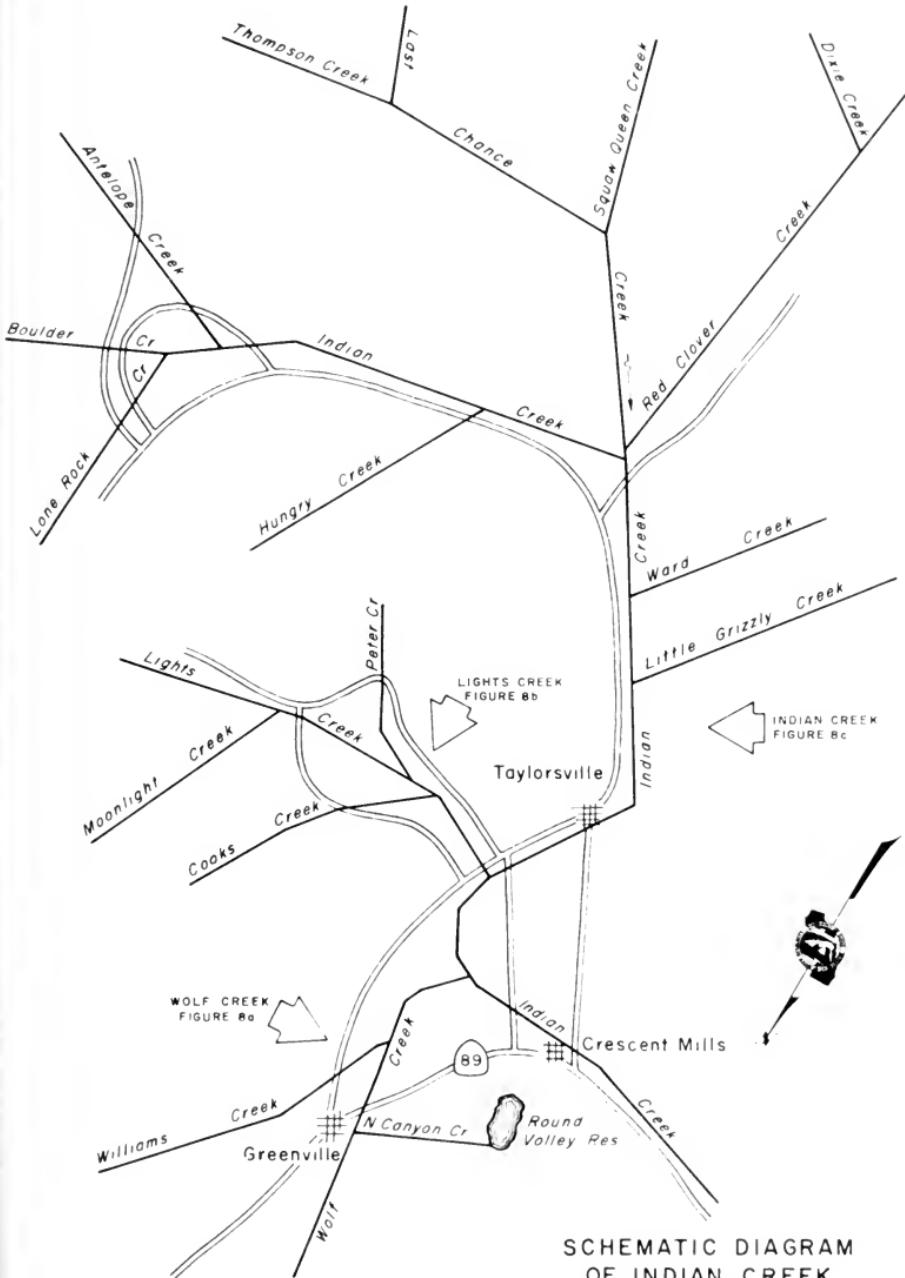

Watermaster service began in the Indian Creek service area on April 27 and continued until September 30. Harvey M. Jorgensen, Water Resources Engineering Associate, was the watermaster during this period.

An above-average water supply existed in the service area during the 1967 season.

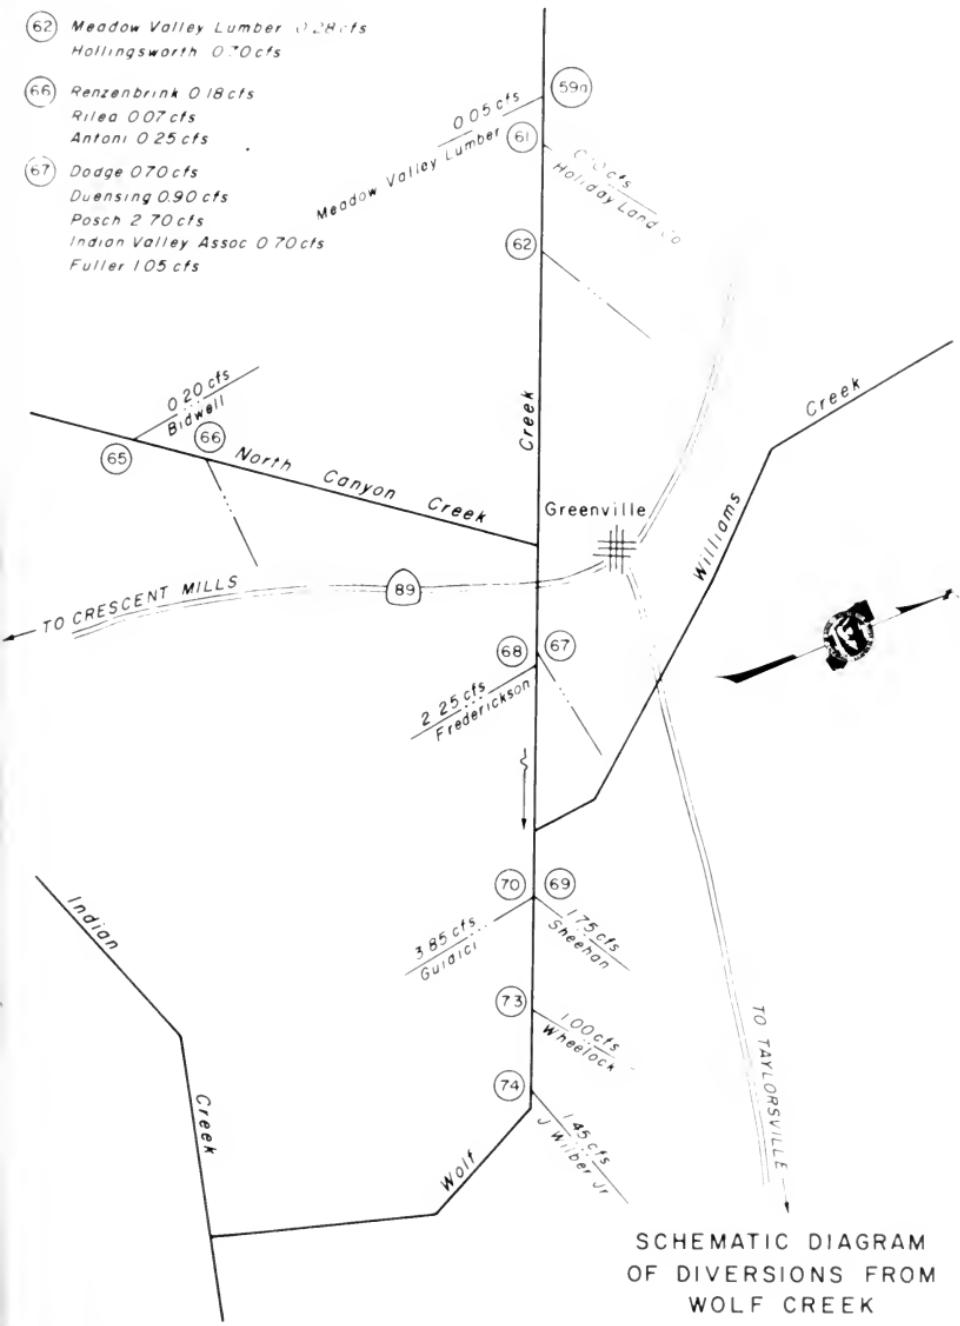

Wolf Creek. The available water supply of Wolf Creek was sufficient to satisfy all allotments (three priorities) until August 15. This supply was quite unusual. Some of the diversion ditches had to be turned off during the season due to over wetting of pastures.

Lights Creek and Tributaries. The water supply of Lights Creek was sufficient to satisfy all allotments (three priorities) until August 1. Flow in both Lights Creek and Cooks Creek remained above normal throughout the season. On August 14 there was two cubic feet per second in Lights Creek and one-half cubic foot per second in Cooks Creek. These observations were made at the county road bridge crossings. The creeks are normally dry in these reaches near the end of June.

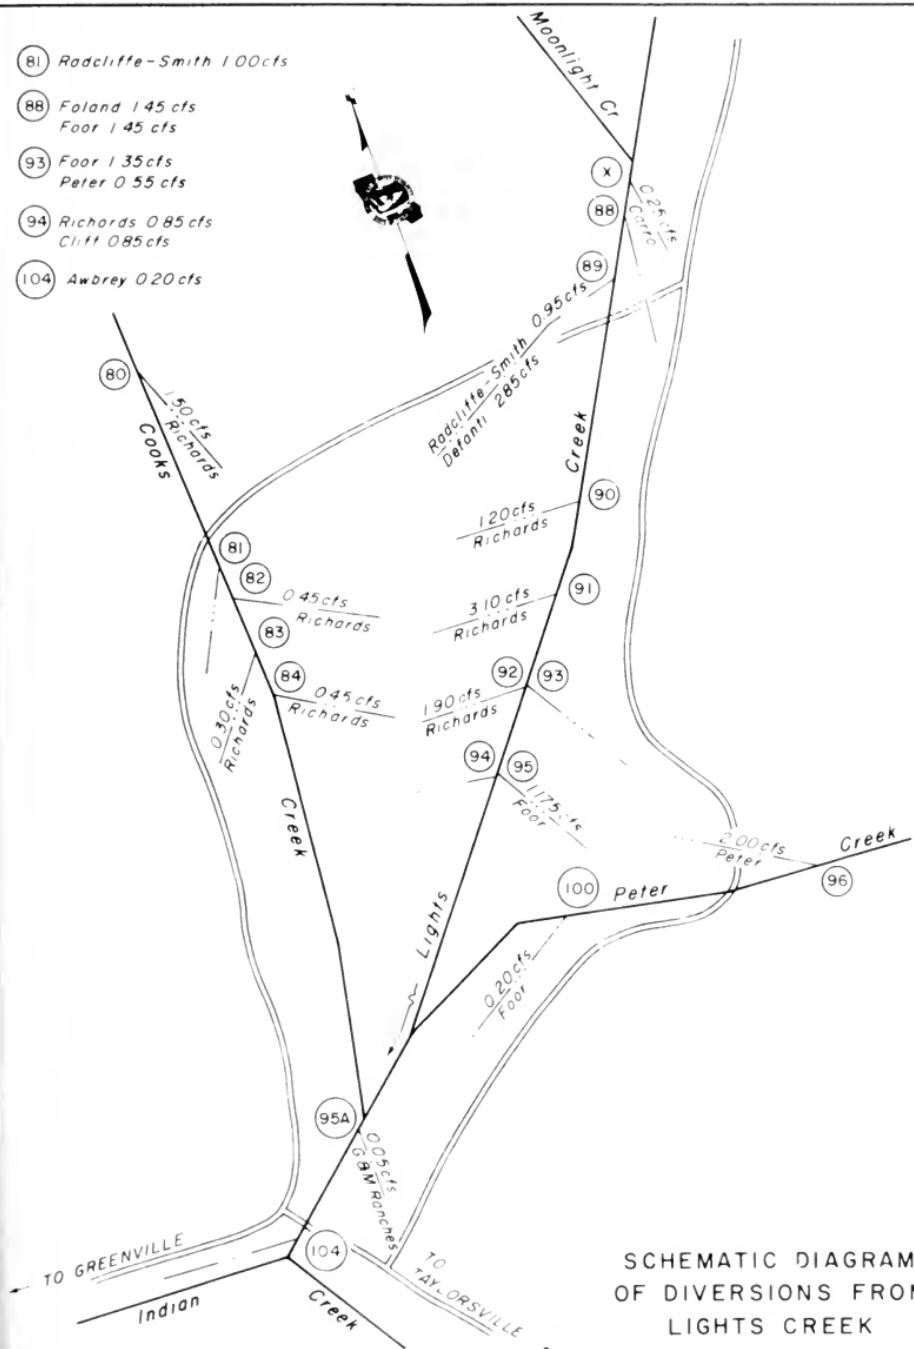

Indian Creek. The available water supply in Indian Creek was sufficient to satisfy all allotments (three priorities) until August 1. On July 24 there was 20 cubic feet per second passing diversion 54, a normally dry reach at that time.

Middle Fork Feather River Watermaster Service Area

The Middle Fork Feather River service area is located in the plateau area on the west slope of the Sierra Nevada in the eastern portions of Sierra and Plumas Counties. There are 96 water right owners with total allotments of 370,365 cubic feet per second.

Major sources of supply for this service area are the Middle Fork Feather River and its tributaries in Sierra Valley. The area is comprised of five major stream groups. These groups, starting in the north and east corner of the valley and proceeding in a southerly and westerly direction, are Little Last Chance Creek, Smithneck Creek, Webber Creek and tributaries, West Side Canal, and Fletcher Creek. The Middle Fork Feather River channel flows in a general northerly direction for approximately 20 miles through Sierra Valley. It then flows in a westerly direction. The major place of use is in Sierra Valley, which is about 15 miles long and 10 miles wide. The average elevation of the valley floor is 4,900 feet.

A schematic drawing of the Middle Fork Feather River service area is presented as Figure 10, page 91.

Water Supply

The major water supply in the Middle Fork Feather River service area is derived from snowmelt runoff, with minor flow from springs and from supplemental stored and foreign water.

Natural flows of Little Last Chance Creek are supplemented by reservoir storage provided by Frenchman Dam which was constructed by the Department of Water Resources in 1961. Stored water is released and used as needed under the provisions of an annual contract. Smithneck Creek flow is normally sufficient to supply all allotments until about the middle of May. It then decreases rapidly until about June 1. Only first and second priority allotments are then available for the remainder of the season.

The natural flow of Webber Creek is normally sufficient to supply all allotments until the middle of May. At that time up to 60 cubic feet per second is diverted from Little Truckee River to supplement the flow. This imported water is diverted through the Little Truckee Ditch into Cold Stream and then into Webber Creek for use by shareholders in the Sierra Valley Water Company. This supplemental supply decreases rapidly during July, producing only a small quantity during the latter part of the season. The West Side Canal streams normally supply all allotments until the first part of June. The flow then gradually declines throughout the season.

The flow of Fletcher Creek and Spring Channels normally supplies all allotments until July 1. The flow then gradually declines for the remainder of the season.

Records of the daily mean discharge of several stream gaging stations in the Middle Fork Feather River service area are presented in Tables 16 through 19, pages 93 through 96.

Method of Distribution

Wild flooding is employed by the majority of the water users to irrigate their fields. Small diversion dams are placed in the stream channels to divert the water into individual distribution systems. Check dams are constructed in the swales to implement flooding once the water reaches the fields.

The Middle Fork Feather River decree (see Table 1) establishes the number of priority classes for each of the major stream systems within the Middle Fork Feather River service area as follows: Little Last Chance Creek - five; West Side Canal Group - five; Fletcher Creek and Spring Channels - three; Sierra Valley Mutual Water Company - one; Webber Creek and tributaries - six; and Smithneck Creek - five.

1967 Distribution

Watermaster service began April 1 in the Middle Fork Feather River service area and continued until September 30. Joe Nessler, Water Resources Engineering Associate, was watermaster during this

period. He was assisted by Conrad Lahr, Water Resource Technician II.

An above-average water supply existed in the service area during the 1967 season.

Little Last Chance Creek. Frenchman Dam and Reservoir began its sixth season of operation in 1967. Agreements concerning storage and distribution were again negotiated with the users in this stream system. The resulting changes in procedures and specific details of distribution and operation are covered in a separate report prepared by the Operations Section of the Sacramento District.

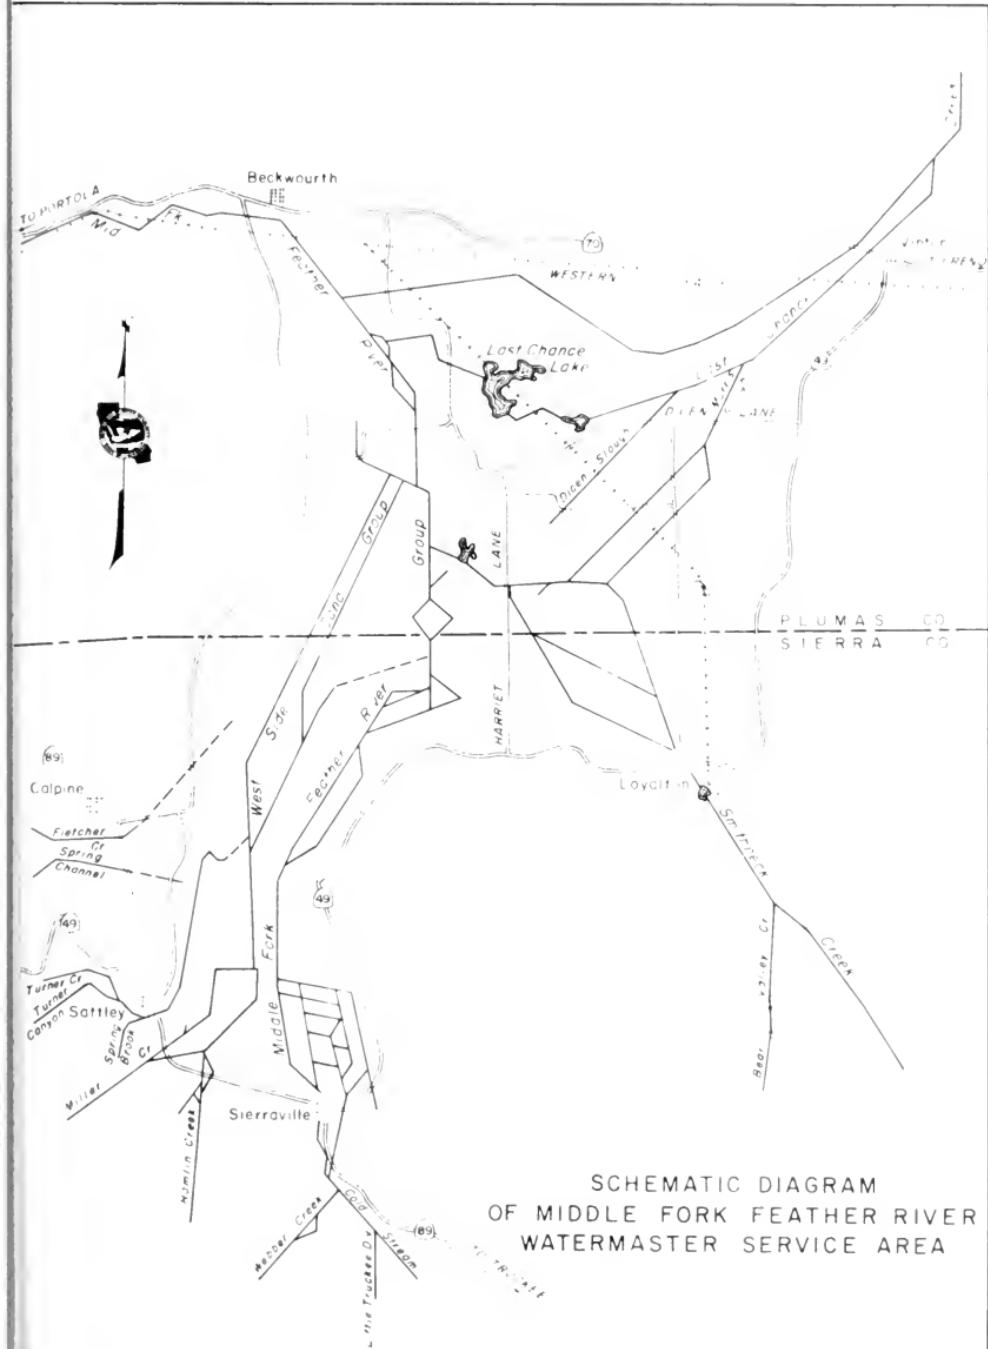

West Side Canal Group. The West Side Canal Group, consisting of Hamlin, Miller, and Turner Creeks, received a sufficient water supply to satisfy all allotments (five priorities) until about August 1. Throughout the remainder of the season the supply was enough to meet demands.

Fletcher Creek and Spring Channels. The available water supply was sufficient to satisfy all allotments (three priorities) throughout the season.

Sierra Valley Mutual Water Company. The Little Truckee Ditch conveyed 2,314 acre-feet of water to the Sierra Valley Mutual Water Company from July 7 through September 30, 1967. Water was distributed to shareholders in accordance with schedule 9 of the Middle Fork Feather River decree.

Webber Creek and Tributaries. The natural flow of Webber Creek was sufficient to supply all allotments (six priorities) until July 1. Combined with the water imported from the Little Truckee River, beginning July 7, the total supply was sufficient to satisfy all allotments of the Sierra Valley Mutual Water Company shareholders until August 1. The natural flow then decreased gradually so that only first and second priority allotments were being served at the end of the season.

Smithneck Creek. The available water supply on Smithneck Creek was sufficient to satisfy all allotments (five priorities) until June 1. Although the flow slowly receded, all demands continued to be met until haying time. Irrigation requirements then dropped sharply. Stockwater was available throughout the remainder of the season. The usual practice of rotation of water rights was not necessary.

North Fork Cottonwood Creek Watermaster Service Area

The North Fork Cottonwood Creek service area is located in the southwestern part of Shasta County near the towns of Ono and Gas Point. There are nine water right owners in the area with total allotments of 30.30 cubic feet per second.

North Fork Cottonwood Creek and its tributaries, Moon Creek and Jerusalem Creek, are the major sources of water supply in the area. These creeks rise on the east slopes of the foothills of the Coast Range Mountains. North Fork Cottonwood Creek flows in a southeasterly direction to its confluence with Cottonwood Creek near Gas Point. The area is characterized by high summer temperatures and moderate rainfall. The irrigable land consists of sparsely scattered parcels separated by steep, brushy hills. These lands are at about the 1,000-foot elevation.

A schematic drawing of the North Fork Cottonwood Creek stream system is presented as Figure 11, page 99.

Water Supply

Snowmelt contributes to the flow in North Fork Cottonwood Creek during the early weeks of the irrigation season. However, perennial springs provide the major source of supply during the summer and fall months. The flow is normally sufficient to supply all demands.

A record of the daily mean discharge of North Fork Cottonwood Creek near Igo is presented in Table 20, page 101. This stream gaging station is located downstream from most points of diversion on the creek but gives a general indication of the water supply.

Method of Distribution

The general practice throughout the area is to irrigate by wild flooding. One water user, however, pumps directly from the creek using a sprinkler system to irrigate his crops. Pumping was necessary at this diversion point because the irrigated land was higher in elevation

than the creek channel.

The North Fork Cottonwood Creek decree (see Table 1) provides for distribution of water on an equal and correlative basis for all users - one priority class.

1967 Distribution

Watermaster service began July 1 in the North Fork Cottonwood Creek service area and continued until September 30. Ross P. Rogers, Water Resources Engineering Associate, was watermaster during this period.

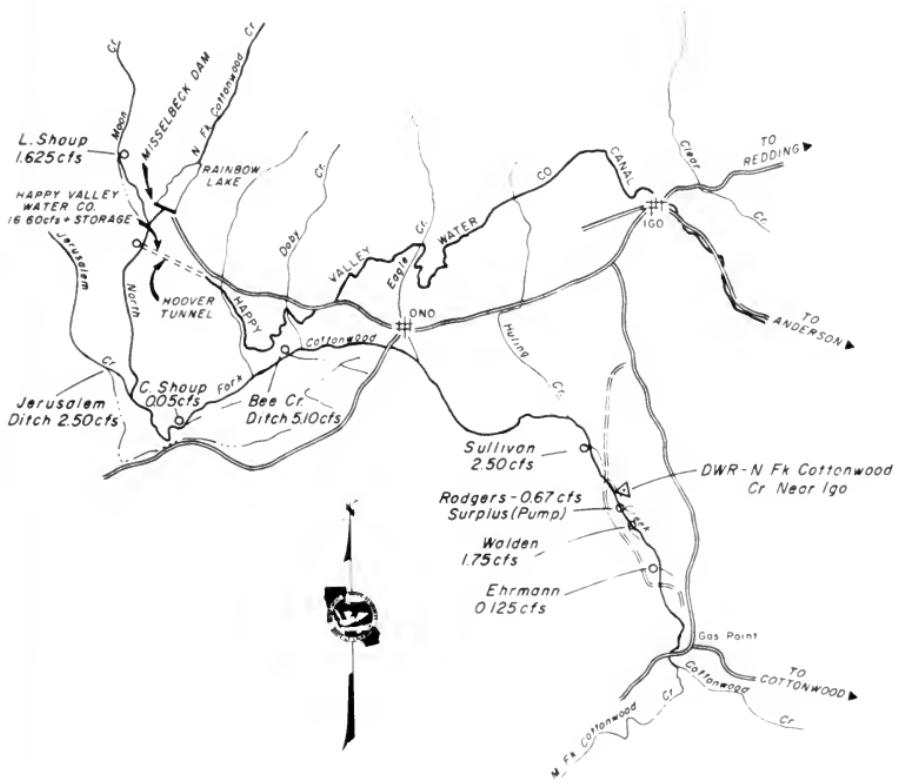

The available water supply in North Fork Cottonwood Creek was outstanding. The stream gaging station near Igo recorded a total of 59,170 acre-feet of runoff between April 1 and September 30. This is approximately 190 percent of the mean for an eleven year period of record.

All demands were met and surplus flows existed throughout the season. Several water right owners, however, did not use any of their allotments.

Special Occurrences

Misselbeck Dam was declared unsafe by the Department of Water Resources' Division of Dam Safety. Therefore, an order was issued to hold the elevation of the lake just above that of the outlet pipes. This may result in some water shortages and distribution problems until satisfactory repairs are made and the reservoir is again allowed to fill.

At the request of a water right owner on Duckett Creek (an area excluded from watermaster service in 1940), a review of the adjudicated water rights was made. This study showed that during critical low-flow periods in August and September, the two existing water rights are essentially independent of each other. Therefore, the area will continue to be excluded from the watermaster service area.

North Fork Pit River Watermaster Service Area

The North Fork Pit River service area lies along the west slopes of the Warner Mountains in northeastern Modoc County and extends from the Oregon border about 45 miles southward to a point just below Alturas. There are 95 water right owners in the area with total allotments of 215,065 cubic feet per second.

A number of small independent stream systems, rising on the west slope of the Warner Mountains and generally following a westerly direction, comprise the major source of water supply. Three of these streams, New Pine Creek, Cottonwood Creek, and Davis Creek, are tributary to Goose Lake. The other streams in the service area are all tributary to the North Fork Pit River. They are: Linville Creek, Franklin Creek, Joseph Creek, Thoms Creek, and Parker Creek. Shields Creek and Gleason Creek are tributaries to Parker Creek. The North Fork Pit River flows in a general southerly course from the south rim of Goose Lake to the confluence with the South Fork Pit River immediately below Alturas. The streams tributary to Goose Lake do not contribute to the flow of the North Fork Pit River since the lake has not spilled into the river for nearly 100 years.

The place of use in the northern half of the area lies in a relatively long, narrow, sloping strip extending between the eastern shore of Goose Lake and the foothills of the Warner Mountains. The places of use in the southern half of the area, consisting of the North Fork Pit River and its tributaries, are primarily in the narrow valleys bordering the streams.

A schematic drawing of each major stream system within the North Fork Pit River service area is presented as Figures 12 through 12k, Pages 109 through 131.

Water Supply

The streams which serve the area are fed by snowmelt runoff and

springs in the Warner Mountains. A large portion of the runoff occurs early in the spring, decreasing rapidly in May and June. The watershed of New Pine Creek, however, is at a higher elevation and maintains a good supply well into the summer. After the snowpack is depleted, perennial springs at the headwaters of the tributaries are the main sources of water supply. Linville Creek, with its small drainage basin, depends almost entirely on the springs at its head. Gleason Creek, Thoms Creek, and Cottonwood Creek are usually dry in August, except during years of above-average water supply.

Some supplemental water is stored in small reservoirs throughout the area, none of which are operated by the watermaster. However, the inflows to some of these reservoirs are under the watermaster's jurisdiction.

Records of the daily mean discharge at several stream gaging stations in the North Fork Pit River service area are presented in Tables 21 through 32, pages 133 through 144.

Methods of Distribution

Irrigation is accomplished primarily by wild flooding from random field ditches along high spots in the meadows. Various types of diversion structures are used to divert the natural streamflow into small earth ditches which convey it to the meadows. At present there is a limited amount of sprinkler irrigation, some by naturally developed pressure and some by direct pumping from small sumps in the ditches. Subirrigation by the use of large flashboard dams to raise the water level in the stream channel is being practiced on the North Fork Pit River between Parker Creek and Alturas.

The several decrees (see Table 1) which apply to the North Fork Pit River service area establish the following number of priority classes for the various stream systems: New Pine Creek - four; Cottonwood Creek - six; Davis Creek - four; Linville Creek - two; Franklin Creek - four; Joseph Creek - four; Thoms Creek - three; Parker Creek - four; Shields Creek - four; Gleason Creek - five; and North Fork Pit River - five.

1967 Distribution

Watermaster service began April 20 in the North Fork Pit River service area and continued until September 30. Charles H. Holmes Assistant Civil Engineer, was watermaster during this period.

The available water supply during the spring months was excellent throughout the service area. Because of a very warm summer, however, streamflows during the latter part of the season were at or near average conditions.

New Pine Creek. Surplus water was available to New Pine Creek water right owners throughout the period that the proration or correlative system of distribution was in effect (until June 30). Commencing July 1, in accordance with provisions of the decree, distribution was based on the priority system (four priorities). Fourth priority allotments received some water until July 23. All third priority allotments were satisfied until August 7. Thereafter, the flow gradually decreased until approximately 70 percent of second priority allotments were being met at the end of the season.

Cottonwood Creek. A sufficient water supply existed in Cottonwood Creek to satisfy all allotments (six priorities) until late spring. The fourth priority allotments were served until late June. Thereafter, the flow decreased gradually, reaching first priority on August 1. By the end of the season the flow had decreased until only about 15 percent of first priority allotments were served.

Davis Creek. The available water supply in Davis Creek was sufficient to satisfy all allotments (four priorities) until June 2. One hundred percent of third priority allotments were served until June 22. The flow then steadily decreased, reaching 100 percent of the second priority allotments on September 1. At the end of the season the flow had receded slightly to 80 percent of first priority allotments.

Linville Creek. The available water supply in Linville Creek decreased steadily from the time watermaster service began until the end of the irrigation season. A small percentage of second priority allotments (two priorities) was supplied from May 18 to May 24. The available supply for first priority allotments ranged between 100 percent

on May 25 to 60 percent at the end of the season.

Franklin Creek. The available water supply in Franklin Creek was sufficient to satisfy all allotments (four priorities) until June 8. One hundred percent of third priorities were served until June 10. The flow then gradually decreased until mid-September when 95 percent of second priority allotments were being served. On September 15 the winter schedule of priorities became effective. Under this schedule, only 50 percent of second priority allotments were met.

Joseph Creek. A surplus water supply existed in Joseph Creek until July 6. The flow then receded rapidly until on July 22 only first priority allotments (four priorities) were served. Thereafter, the flow gradually decreased to 50 percent of first priority allotments at the end of the season.

Thoms Creek. A sufficient water supply existed in Thoms Creek to meet all allotments (three priorities) until July 11. The flow then gradually decreased to 6 percent of third priority allotments at the end of the season.

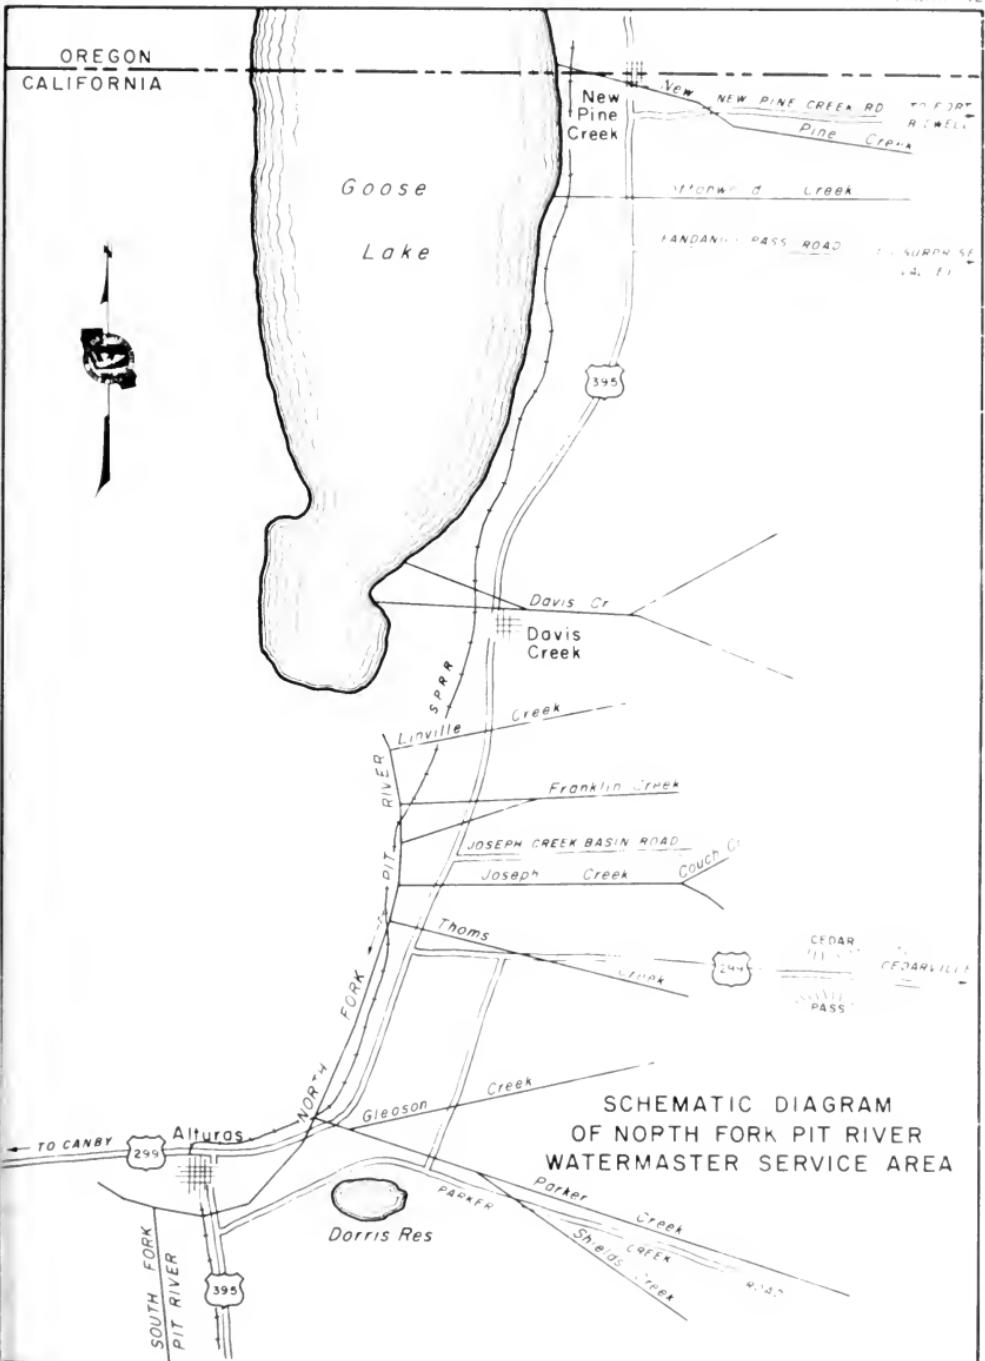

Gleason Creek. The available water supply in Gleason Creek was sufficient to satisfy fourth priority allotments (five priorities) until June 2. The flow then rapidly dropped to 100 percent of second priority allotments by July 13. By late July the creek was dry.

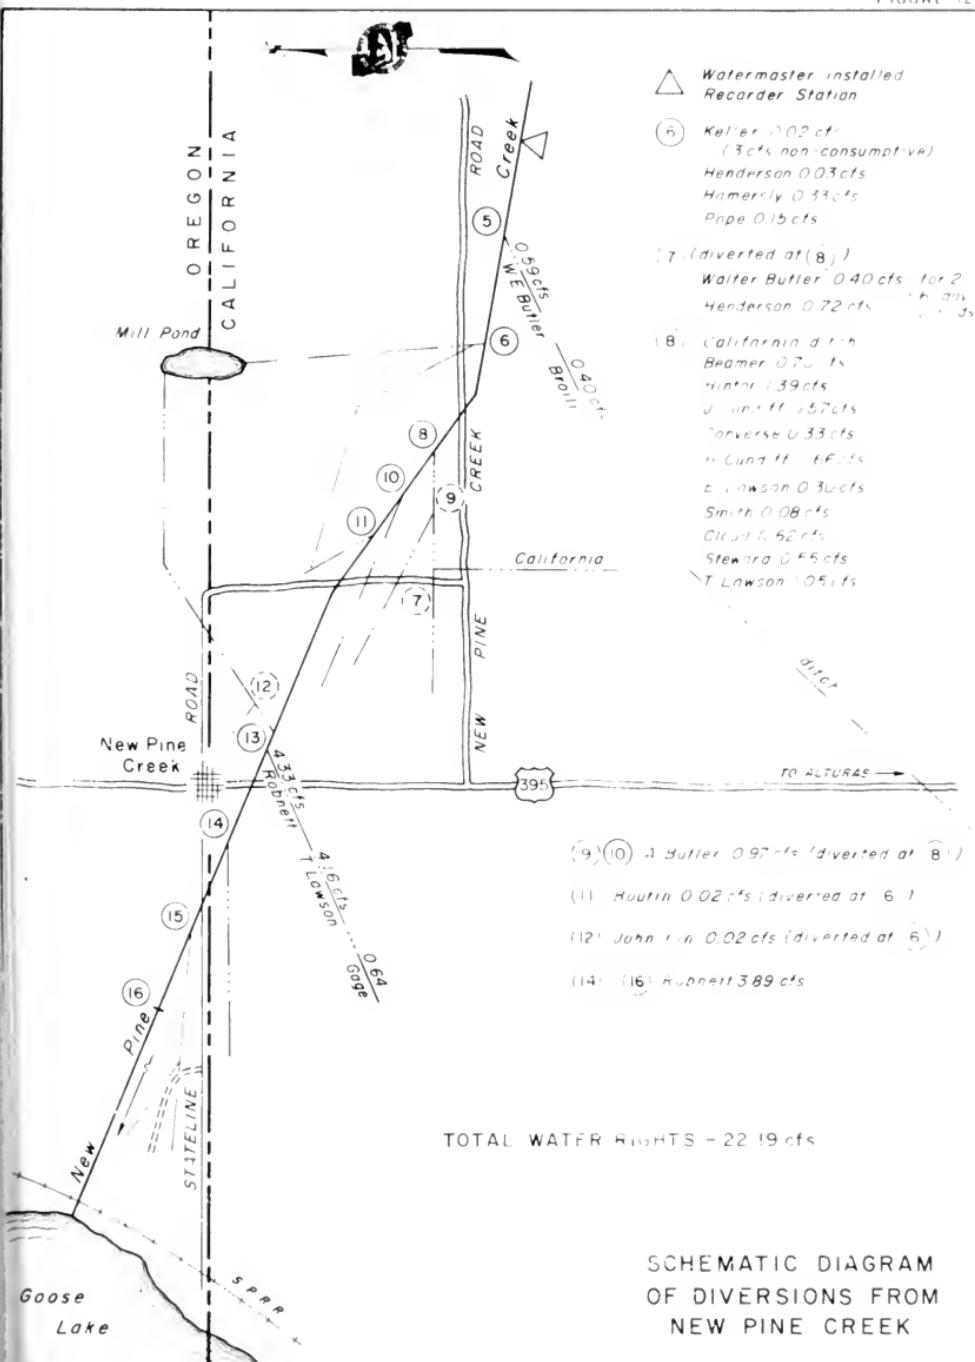

Shields Creek. A surplus water supply existed in Shields Creek until July 1. The flow decreased rapidly until approximately 75 percent of first priority allotments (four priorities) were served on September 1. The supply then gradually increased until the end of September when 60 percent of second priority allotments were being supplied.

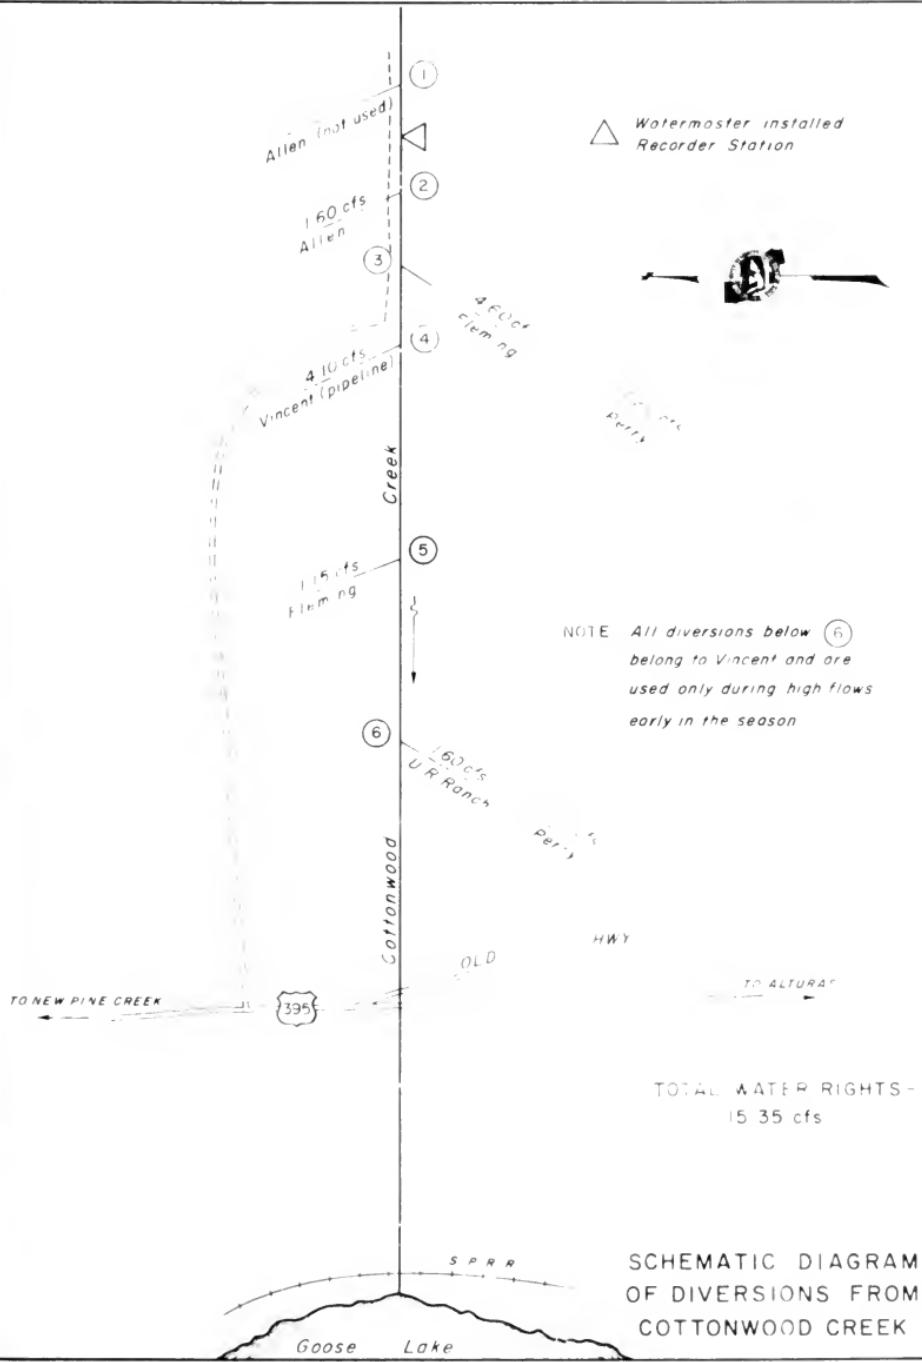

Parker Creek. The flow in Parker Creek peaked in mid-May. It then decreased steadily until July 14 when 100 percent of all allotments (four priorities) were served. From then until the end of July the flow continued to decrease gradually. Throughout the remainder of the season the flow remained constant at 15 percent of third priority allotments.

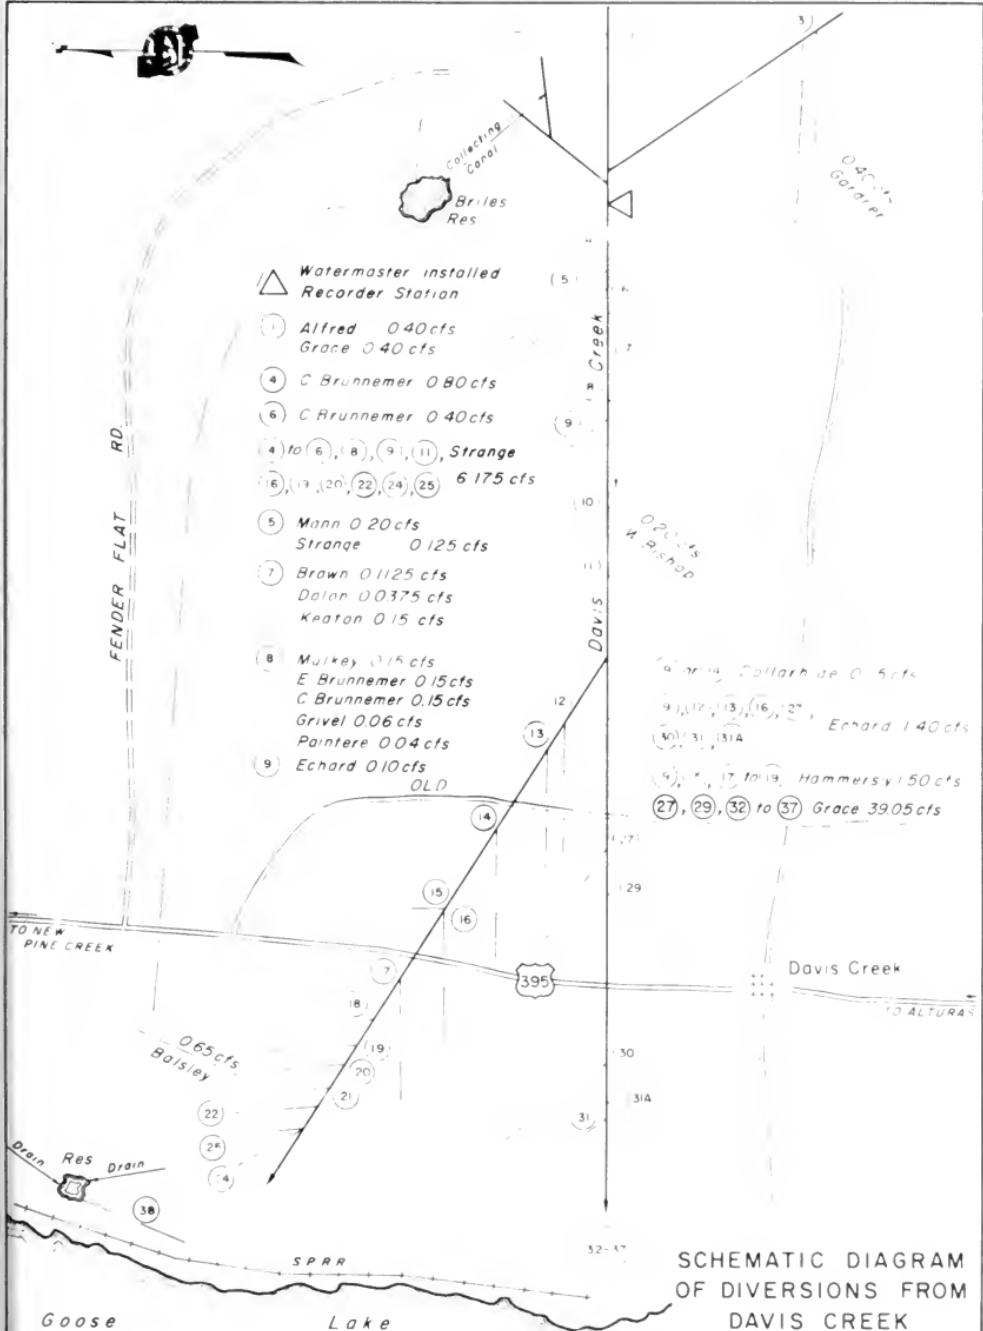

North Fork Pit River. A surplus water supply existed in the North Fork Pit River until June 24. On that date the Dorris Reservoir

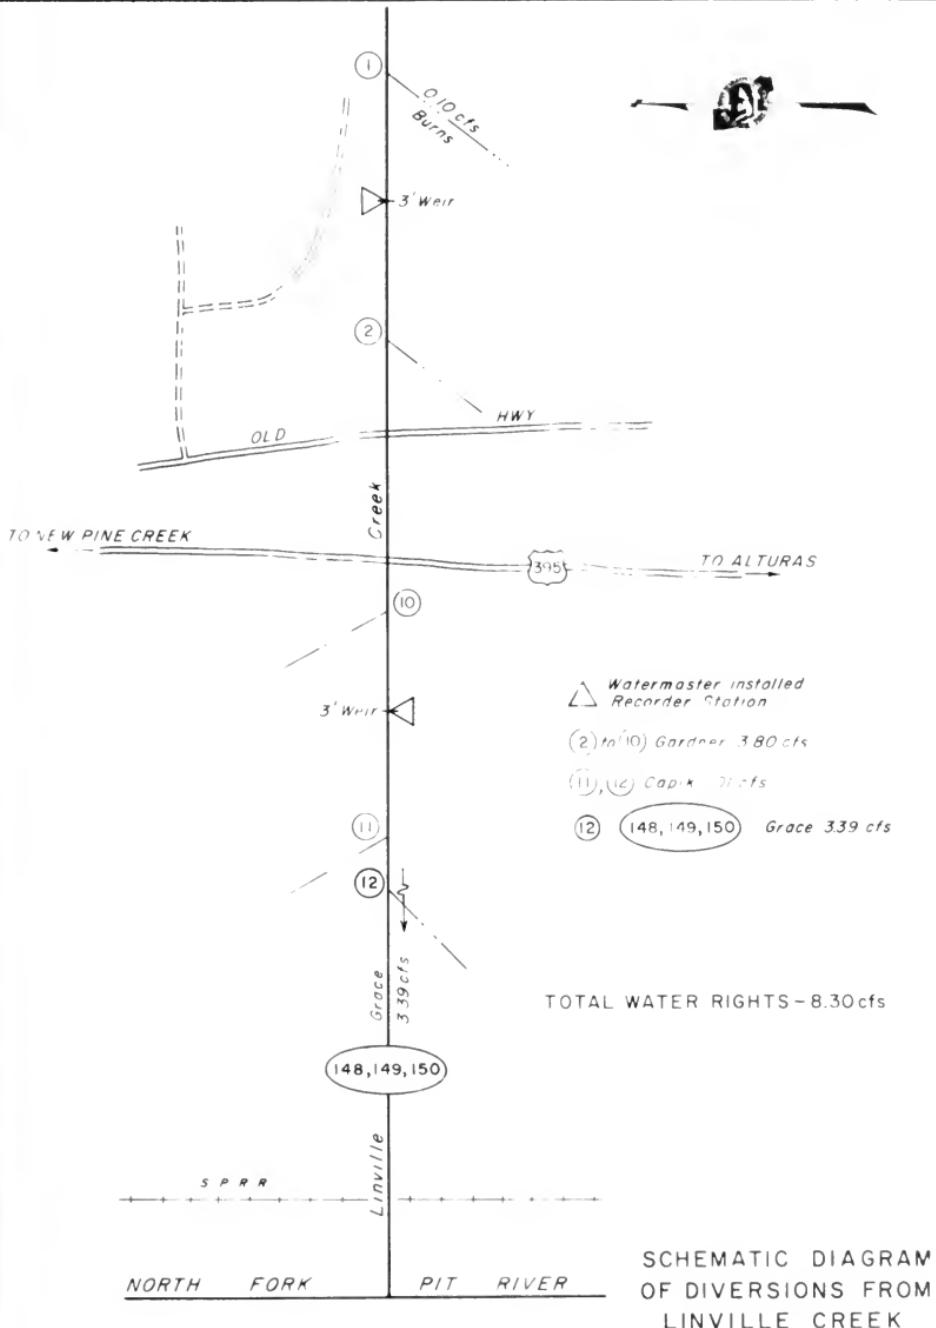

allotment was reduced. The flow then decreased rapidly until June 19 when only first priority allotments (five priorities) were being served. The decrease continued until July 19 when only stockwater was available. This condition continued throughout the remainder of the season.

Shackleford Creek Watermaster Service Area

The Shackleford Creek service area is located in western Siskiyou County near the town of Fort Jones in Scott Valley. There are 21 water right owners in the service area with total allotments of 63.98 cubic feet per second. The major sources of water supply for this service area are Shackleford Creek, which flows through the central part of Quartz Valley, and its tributary, Mill Creek, which rises east of the headwaters of Shackleford Creek. Evans Creek, a small tributary to Mill Creek, enters from the south.

The service area encompasses the Quartz Valley region of Scott Valley and includes the entire agricultural area within the Shackleford Creek Basin. It is about two miles wide by six miles long with the main axis and drainage running from south to north. Elevations on the agricultural area range from about 3,100 feet at the south to about 2,650 feet at the confluence of Shackleford Creek and Scott River.

A schematic drawing of the Shackleford Creek stream system is presented as Figures 13 and 13a, pages 147 and 148.

Water Supply

The water supply for Shackleford Creek is derived from snowmelt runoff, springs and seepage, and supplemental stored water released from Cliff Lake and Campbell Lake. These lakes are located near the headwaters of Shackleford Creek.

The watershed of the Shackleford Creek stream system contains about 31 square miles, located in the heavily forested, steep, mountainous terrain of the northeasterly slopes of the Salmon Mountains. It varies in elevation from about 7,000 feet along its west rim to about 3,000 feet at the foot of the slopes bordering Quartz Valley.

Snowmelt runoff is normally sufficient to supply all demands until the middle of July. The supply then usually decreases until the

first part of August when water is released from Cliff and Campbell Lakes to maintain sufficient flow for second priority allotments in the Shackleford Ditch.

There were no stream gaging stations operated in the Shackleford Creek service area during 1967. However, several stations were maintained in various diversion ditches.

Method of Distribution

Irrigation is accomplished primarily by wild flooding of permanent pasture and alfalfa fields. Water is distributed by ditches and laterals to the places of use. Shackleford Ditch, the largest of these ditches, has a length of about six miles and a capacity of about 12 cubic feet per second.

The Shackleford Creek decree (see Table 1) provides four separate areas of distribution within the service area and establishes the following number of priority classes for these areas: Upper Shackleford Creek - seven; Lower Shackleford Creek - seven; Upper Mill Creek - three; and Lower Mill Creek - two.

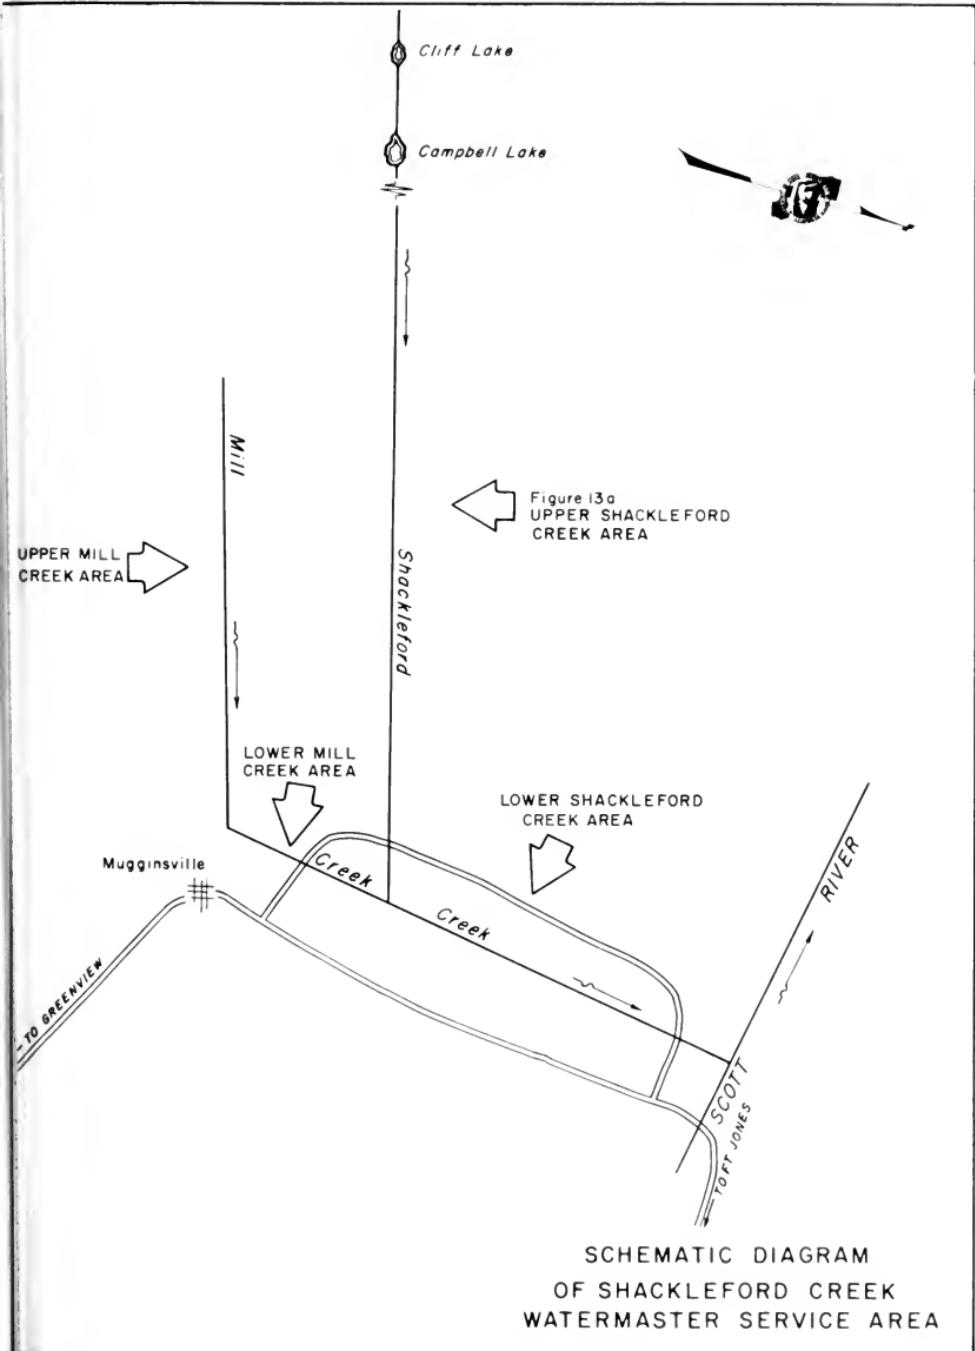

1967 Distribution

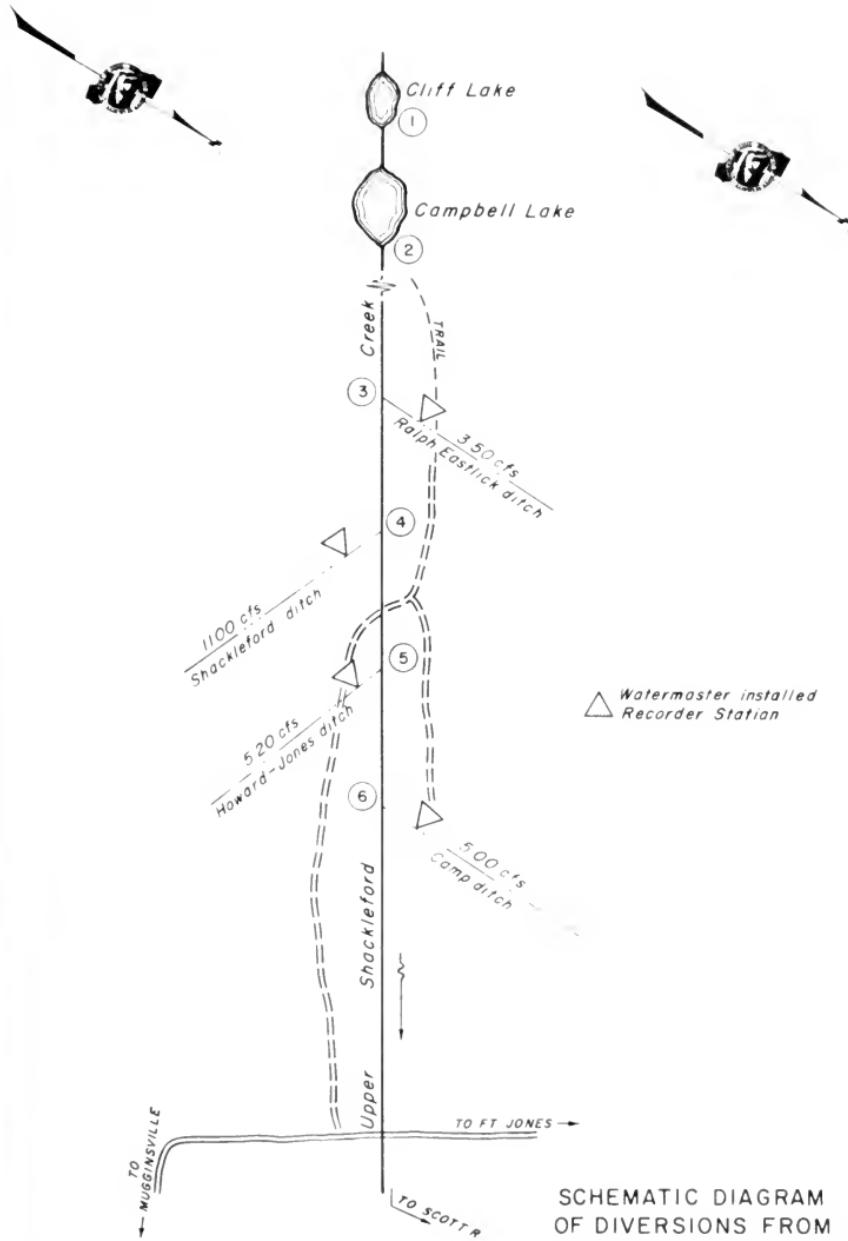

Watermaster service began June 1 in the Shackleford Creek service area and continued until September 30. Harold B. German, Water Resources Engineering Associate, was watermaster during this period.

The available water supply was above normal early in the season but only about normal after August 1. Water right owners in the Howard-Jones Ditch did not use any of their water during the 1967 season. Their fourth priority allotments (seven priorities in the service area) were therefore available for use by owners of lower priorities.

Special Occurrences

New weirs were installed in the upper three diversions this season, and the weir and recorder station on the Ralph Eastlick Ditch was moved upstream. Logging activities above the former station caused it to fill with sand and gravel, thus necessitating the new location.

SCHEMATIC DIAGRAM
OF DIVERSIONS FROM
UPPER SHACKLEFORD CREEK

Shasta River Watermaster Service Area

The Shasta River service area is located in the central part of Siskiyou County, south and east of the town of Yreka. There are 108 water right owners in the service area with total allotments of 594,612 cubic feet per second.

The source of water supply is Shasta River and its several tributaries. The upper reaches of the service area are served by two groups of tributaries. One group, comprising Boles, Beaughan, Carrick, and Jackson Creeks, rises on the northwestern slopes of Mount Shasta. The other group, consisting of Dale and Eddy Creeks, and Shasta River west of U. S. Highway 99, rises on the eastern slopes of the Trinity Mountains. All these streams join the main stem of the Shasta River above Dwinnell Reservoir near the town of Weed. As the Shasta River flows northward from Dwinnell Reservoir to its confluence with the Klamath River, north of Yreka, it is joined by three major tributaries. Parks Creek, rising on the eastern slopes of the Trinity Mountains, enters from the west near the town of Gazelle. Big Springs Creek, from Big Springs Lake, enters from the east about a mile below Parks Creek. Little Shasta River, rising on the western slopes of the mountainous area between Butte Valley and Shasta Valley, enters from the east near the town of Montague.

The place of use is in Shasta Valley which is approximately 30 miles long and 30 miles wide. The valley has numerous small, cone-shaped, volcanic hillocks scattered throughout its central portion that produce the effect of dividing the area into a number of distinctively separate parts. Because of these formations only about 141,000 acres of the approximately 507,000 acres within the valley are irrigable. The valley floor elevation averages approximately 3,000 feet.

A schematic drawing of each major stream system within the Shasta River service area is presented as Figures 14 through 14i, pages 157 through 175.

Water Supply

The water supply for Shasta Valley is derived from snowmelt runoff, springs and underground flow, and occasional summer thunder showers. In several portions of the stream system the spring and underground flow is adequate to supply most allotments throughout the season. Much of the underground flow is derived from the northern slopes of Mount Shasta, which rises to an elevation of 14,162 feet at the south end of Shasta Valley. Although the snowpack on Mount Shasta is usually heavy, there is negligible surface runoff.

Parks Creek, Upper Shasta River, and Little Shasta River derive a major portion of their water supply from snowmelt runoff. This flow is usually adequate to supply all allotments until the middle of May.

Beaughan Creek, Carrick Creek, Shasta River from Boles Creek to Dwinnell Reservoir, Big Springs, and Lower Shasta River have enough runoff from springs to supply a large percentage of the allotments throughout the season.

Records of the daily mean discharge at several stream gaging stations in the Shasta River service area are presented in Tables 33 through 39, pages 177 through 183.

Methods of Distribution

Irrigation of permanent pasture and alfalfa lands is accomplished principally by wild flooding. Much of the return water is recaptured and used on lower pasture lands. Sprinkling systems are used for irrigating some alfalfa and grain lands.

Water is diverted primarily by diversion dams and then conveyed by ditch or canal to the place of use. The largest and longest canal in the area is the Edson-Foulke Yreka Ditch, which has a capacity of about 60 cubic feet per second and a length of about 15 miles. Water is also supplied into ditch systems by pumped diversions. The largest of these belong to three irrigation districts. Several riparian water right owners also use pump diversions.

Many privately owned storage reservoirs exist in the area.

Water storage from these reservoirs is used to supplement continuous flow allotments.

The Shasta River decree (see Table 1) provides eight separate areas of distribution within the service area. This decree established the following number of priority classes for these areas: Shasta River above the confluence with Big Springs Creek - 43; Boles Creek - 20; Beaugham Creek - 5; Carrick Creek - 13; Jackson Creek - 7; Parks Creek - 25; Shasta River below the confluence with Big Springs Creek - 29; and Little Shasta River - 7.

Three privately operated water districts within the service area have main diversions which are under supervision of the watermaster. These are: Shasta River Water Users Association, Grenada Irrigation District, and Big Springs Irrigation District. A fourth, the Montague Water Conservation District, stores water in Dwinnell Reservoir for use by the District and by natural flow water right owners immediately below the dam. The watermaster is responsible for diversion to these users.

A number of riparian water users along the Lower Shasta River were not included in the Shasta River decree. Owners of these undefined water rights are therefore not subject to watermaster supervision; consequently, in seasons of short supply these rights can be the cause of many water distribution problems.

1967 Distribution

Watermaster service began April 2 in the Shasta River service area and continued through September 30. Harold B. German, Water Resources Engineering Associate, was watermaster during this period.

The available water supply in the service area was generally above average during the season.

Parks Creek. The flow in Parks Creek was sufficient to supply all allotments (25 priorities) until early July. Some water continued to be diverted into the Yreka Ditch until August 20. The first priority allotments of six cubic feet per second were available for the entire season. Water users downstream from the lowest first priority diversion

received a portion of their allotments during the latter part of the season from return flow and from water rising in the gravel streambed.

Upper Shasta River. The water supply in this area (including Dale and Eddy Creeks), which depends almost entirely on snowmelt runoff, was above average for the season. However, an unusually warm summer caused the minimum runoff occurring in September of 1967 to be less than it was in 1966, a dry season.

During early spring, enough water was available to satisfy all allotments (eight priorities). As the flow decreased, the following levels of priority allotments were met: July 18 - all of fourth priority; July 23 - all of the third priority (Yreka Ditch main allotment); and September 4 (the seasonal low) - 16 percent of the third priority.

Shasta River from Boles Creek to Dwinnell Reservoir. Boles Creek and Shasta River from Boles Creek to Dwinnell Reservoir were operated as one stream, under a long standing oral agreement among the water right owners, with water being distributed on an equal and correlative basis. Adequate water was available to satisfy all allotments until the middle of August. All diversion were then cut to 80 percent. Early in September the flow increased to again allow diversion of 100 percent.

Beaughan Creek. The flow of Beaughan Creek was sufficient to satisfy most demands (five priorities) for the entire season. The creek is routed through a mill pond owned by the International Paper Company which uses approximately 35 percent of the flow for industrial purposes.

Carrick Creek. The water supply in Carrick Creek was adequate to satisfy all allotments (13 priorities) during the entire irrigation season.

Little Shasta River. Enough water was available in the Little Shasta River to satisfy all fifth priority allotments (seven priorities) until early in July. After that date close regulation became necessary to adequately distribute this priority. The flow continued to decrease to approximately 20 percent of fifth priority allotments by the first week in August. It then stayed constant for the remainder of the season.

The daily mean discharge of Little Shasta River near Montague

is presented in Table 38, page 182. This runoff is augmented by rising water along the river channel, and by substantial inflow from Cleland Springs, a tributary approximately two miles below the stream gaging station. Therefore, considerably more water is usually available for distribution at downstream diversion points than is indicated in the discharge table.

Dwinnell Reservoir. Releases from Dwinnell Reservoir to the Montague Water Conservation District commenced on April 26 and continued into October. Reservoir operation data for the 1967 season are shown in Tables 35 and 36, pages 179 and 180.

By agreement with the Montague Water Conservation District water users on Shasta River below Dwinnell Reservoir received stored water from the reservoir on demand in lieu of their natural flow rights. The agreement allotment totals and the amount delivered to each user this season are shown in the following tabulation:

DELIVERIES TO NATURAL FLOW WATER RIGHT OWNERS
BELOW DWINNELL RESERVOIR - 1967

Name of Water Right Owner	Allotment in Acre-feet	Amount Delivered From Dwinnell Reservoir Acre-feet	% of Allotment
Flying L. Ranch	198	198	100
Frank Ayers	464	464	100
J. N. Taylor	1,200	1,073	89
W. W. Valentine			
Hole-in-the-Ground Ranch	596	0	0
Seldom Seen Ranch	924	702	76
TOTALS	3,382	2,437	72

Big Springs. Due to the late, cold spring, the flow of Big Springs was below normal. This shortage of water and a misunderstanding about the maximum allowable surface elevation of Big Springs Lake, caused some operational problems early in the season.

During July, August, and September the flow in Big Springs increases as snowmelt from higher elevations on Mount Shasta percolates into the ground and reappears as surface flow at Big Springs Lake. As a result, Big Springs Irrigation District, a third priority water right owner, was able to pump its full allotment during August and September.

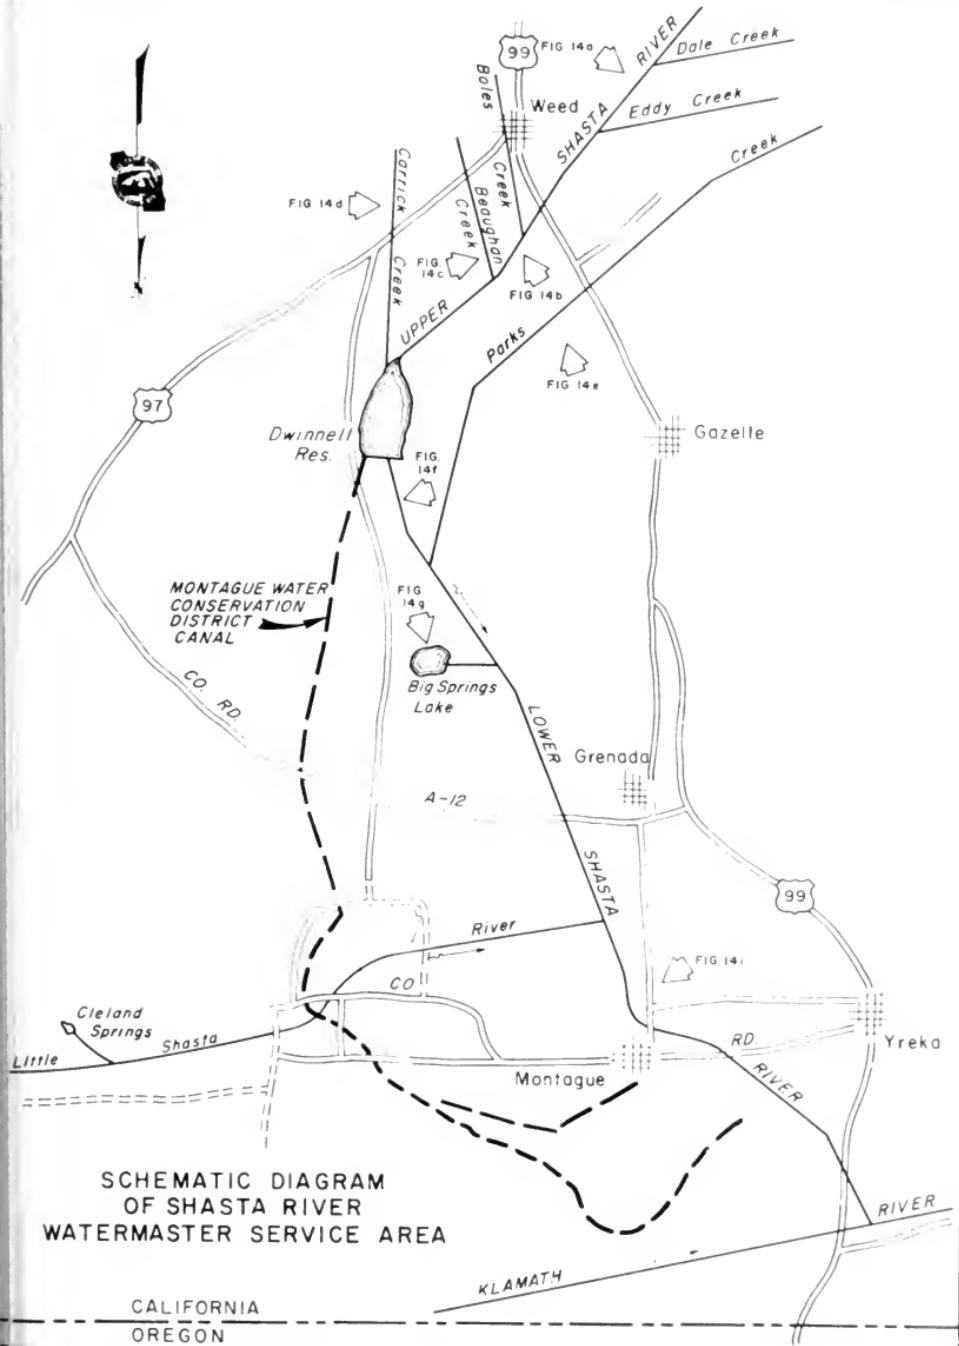

Lower Shasta River. The water supply in Lower Shasta River was sufficient to satisfy all allotments (29 priorities) for the entire season. During the first week in August the flow reached its low for the season at just over 100 percent of allotments. It then increased, providing surplus water for the remainder of the season.

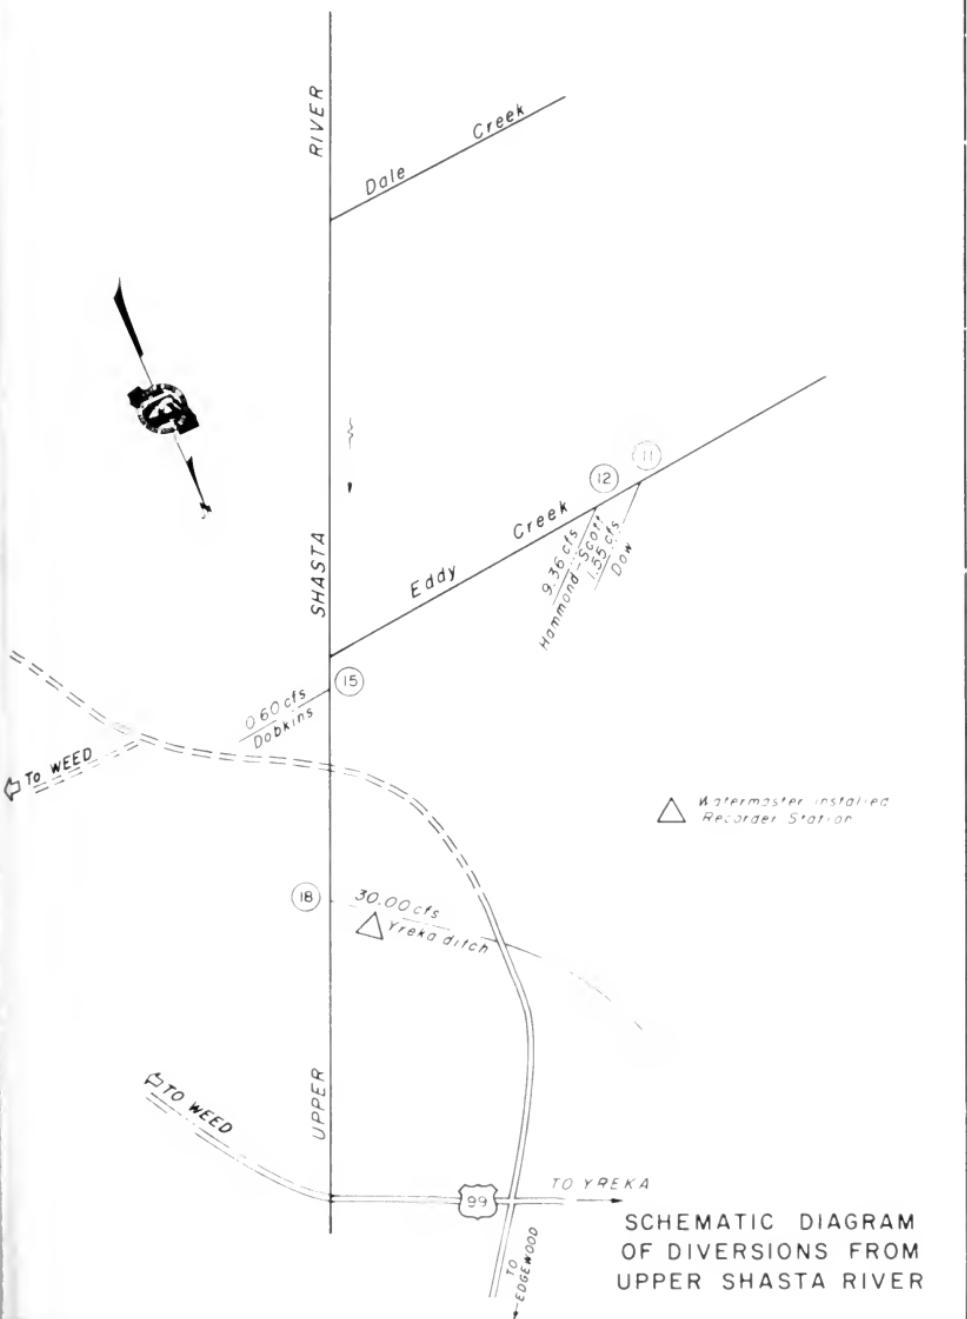

Special Occurrences

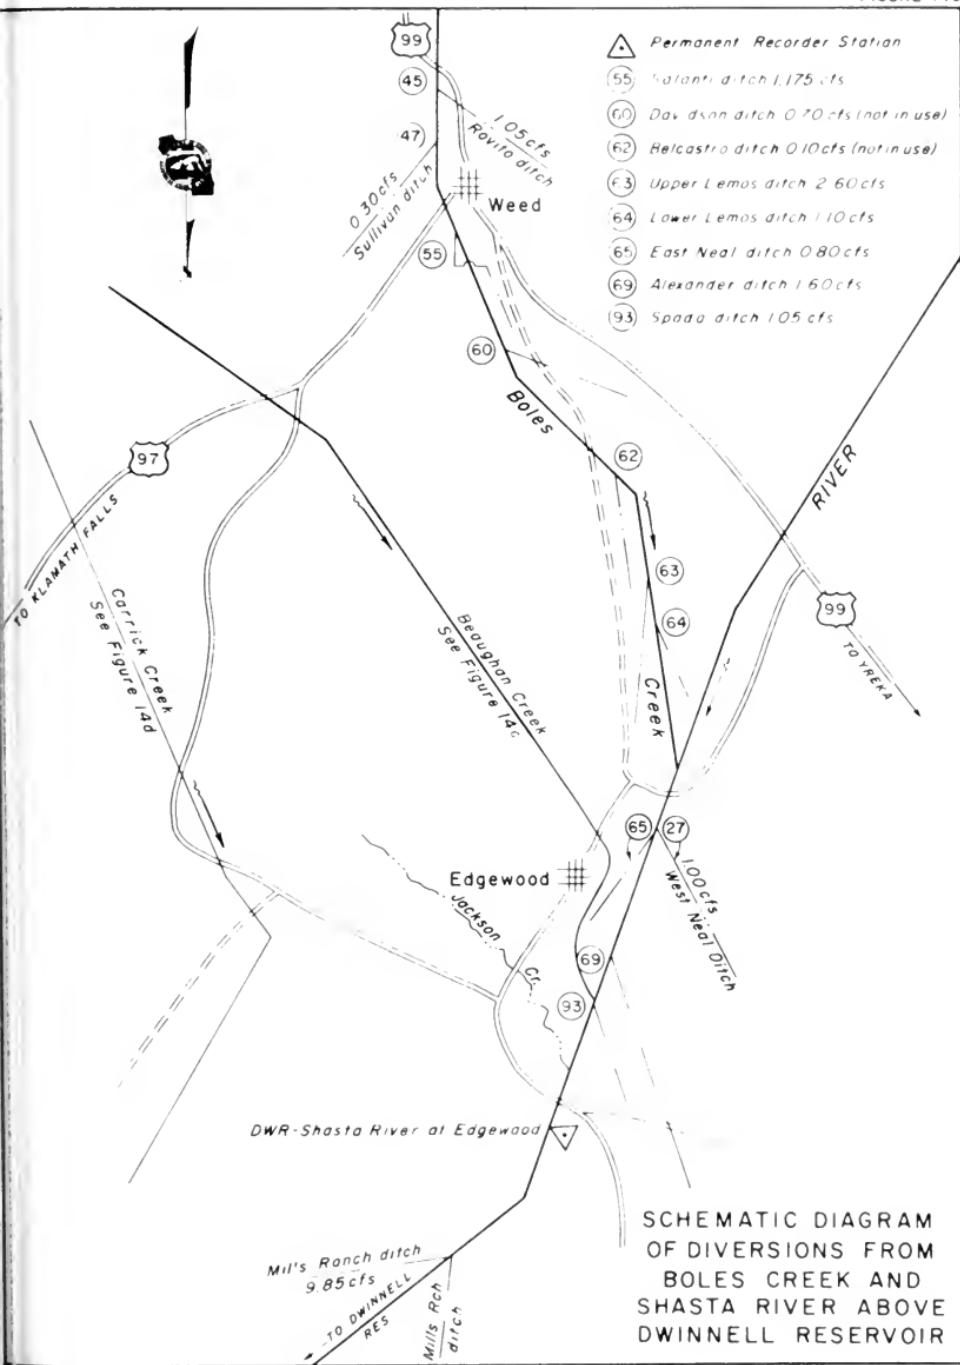

Three water control devices were constructed in the Shasta River service area during the season.

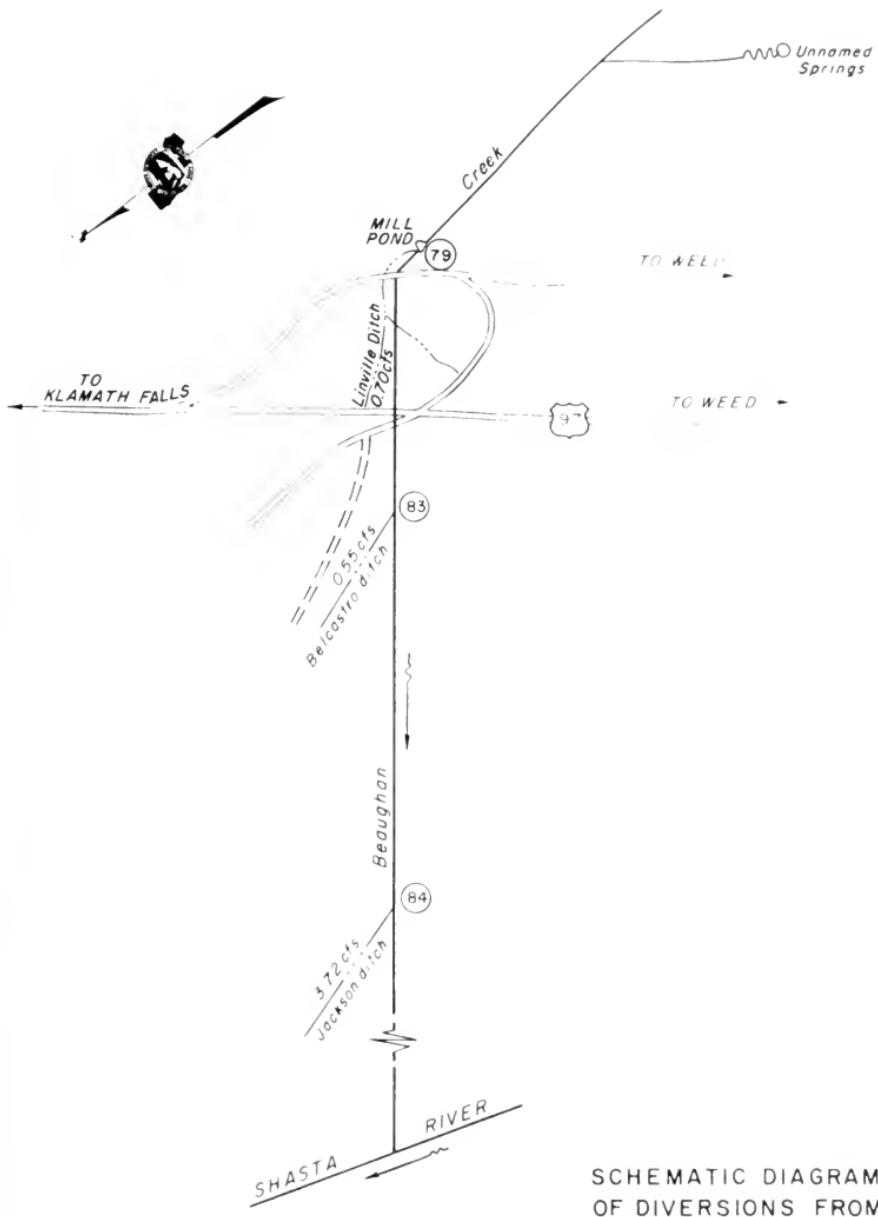

A concrete headwall with a metal screw-type headgate was built in the Dimmick Ditch near its point of diversion from Little Shasta River. A concrete structure, providing a continuous automatic division of water rights, was built in the Hart, Haight, and Prather Ditch which also diverts from Little Shasta River.

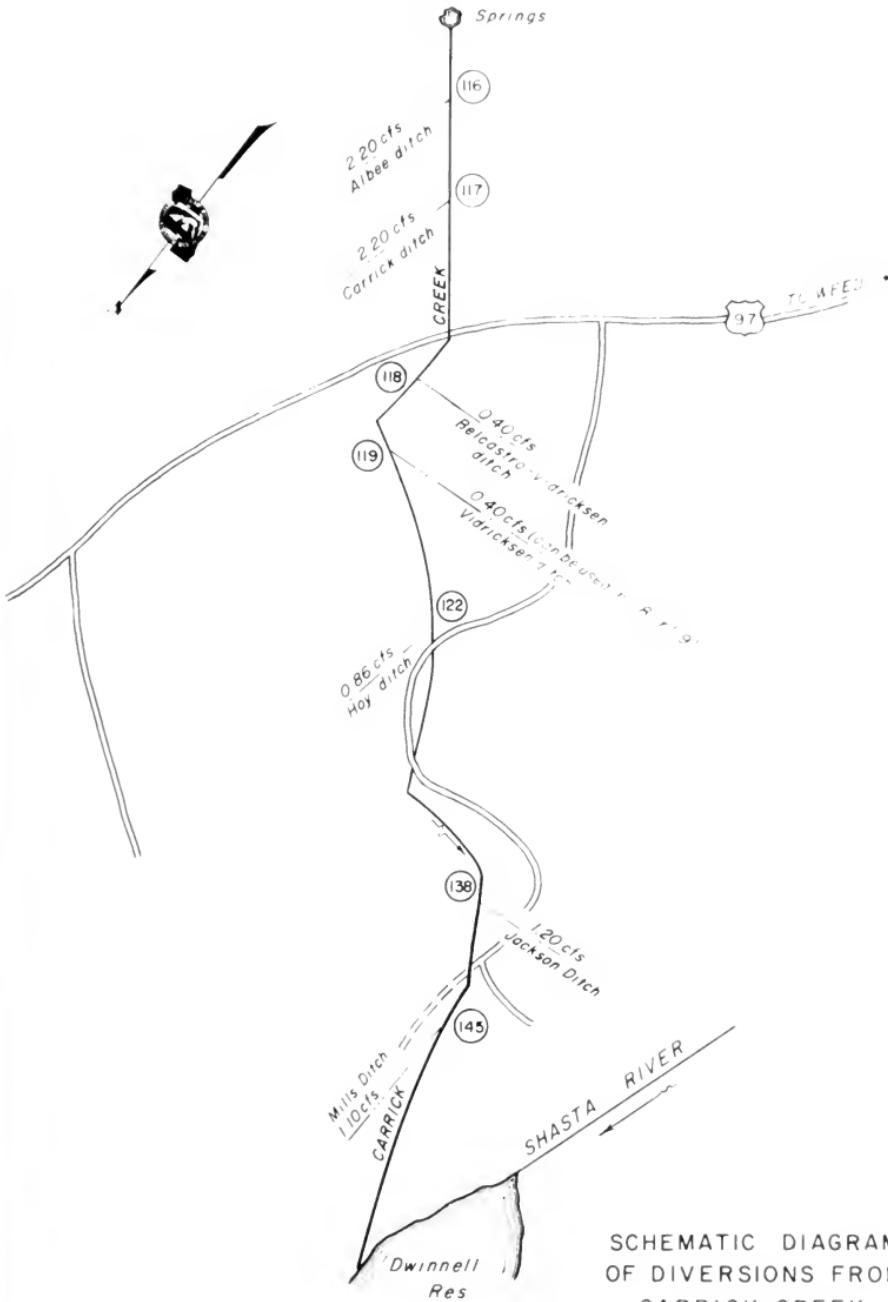

A concrete division structure was built in the Ayers and Hole-in-the-Ground Ranch diversion ditch from Shasta River immediately below Dwinnell Reservoir.

South Fork Pit River Watermaster Service Area

The South Fork Pit River service area is located primarily in Modoc County with a small portion extending into the northern part of Lassen County. There are 37 water right owners in the area with total allotments of 350.97 cubic feet per second.

Water supply for this service area is obtained from the South Fork Pit River and its tributaries which rise on the western slopes of the Warner Mountains. The river flows in a westerly direction, entering South Fork Valley near Likely. It then flows north through the valley to its confluence with the North Fork Pit River at Alturas. The South Fork Pit River is joined from the east by Fitzhugh Creek near the middle of the valley and by Pine Creek just south of Alturas.

The major area of water use is in South Fork Valley between Likely and Alturas. South Fork Valley is about 16 miles long and 3 miles wide with the valley floor lying at an elevation of about 4,500 feet. The valley is bounded on both sides by a rocky plateau that separates it from the surrounding mountains.

A schematic drawing of each major stream system within the South Fork Pit River service area is presented as Figures 15 through 15d, pages 189 through 197.

Water Supply

The water supply for Pine Creek is derived mostly from snowmelt runoff. Therefore, runoff is usually small in the early spring, increases to a peak in May as temperatures rise, and then gradually decreases throughout the remainder of the season. Water users supplement their irrigation supplies from other sources whenever possible.

The water supply for Fitzhugh Creek consists of snowmelt runoff early in the season and supplemental water diverted from Mill Creek above Jess Valley later in the season. Surplus water from Fitzhugh Creek is diverted into the Payne and French Reservoirs through

Payne-French Ditch (Diversion 136) until about June, when the diversion is closed to supply downstream allotments. By July the creek has normally receded until only first priority allotments are available.

Payne Ditch (Diversion 1) is opened to import water from Mill Creek to Fitzhugh Creek when the snow has melted enough to allow access. This imported water is redirected from North Fork Fitzhugh Creek through the Bowman Ditch to the Bowman Ranch. Return flow from Bowman Ranch to the creek is redirected through diversion 136 for stockwatering purposes in the Payne-French Ditch.

The water supply for the South Fork Pit River is derived primarily from snowmelt runoff, supplemented by water released from West Valley Reservoir. A number of streams, which rise at high elevations, collect at the mouth of Jess Valley to form the South Fork Pit River. West Valley Reservoir is located on West Valley Creek which enters the river below Jess Valley.

Most of the water users on the South Fork Pit River, except those in Jess Valley, are in the South Fork Irrigation District. The district stores water in West Valley Reservoir, which has a capacity of 22,240 acre-feet, and releases it to the South Fork Pit River as a supplemental supply when the natural flow becomes insufficient to meet demands. This usually occurs during the middle of June. Reservoir releases, together with the natural flow, are distributed by the watermaster in cooperation with the Board of Directors of the irrigation district. Except for extremely dry years natural flow, combined with stored water, is sufficient to supply all demands for water on the South Fork Pit River throughout the irrigation season.

Records of the daily mean discharge of the several stream gaging stations in the area are presented in Tables 40 through 43, pages 199 through 202.

Methods of Distribution

Irrigation of the lands along tributary stream is accomplished by flooding through use of small lateral ditches. The water is distributed on a continuous-flow basis to each user through gravity

flow diversion systems. In some cases, rotation is practiced among several users.

Most irrigation in the South Fork Pit River area is by the check and border method. The lands receive water essentially on demand by supplementing natural flow with releases from West Valley Reservoir. However, irrigation between the various ranches must be coordinated to eliminate large peak demands from the reservoir and to use the return flow as much as possible. Actual distribution varies each year as there is no specific irrigation schedule in use.

The South Fork Pit River decree and the Pine Creek Agreement (see Table 1) establish a two-priority class system of distribution for the Fitzhugh Creek and Pine Creek stream systems. Distribution to the South Fork Pit River users (the decree provides for a two-priority class system) is carried out on an equal and correlative basis in accordance with the water requirements for each ranch. This method of operation was made possible by construction of West Valley Reservoir in 1937.

1967 Distribution

Watermaster service began April 1 in the South Fork Pit River service area and continued until September 30. George H. Pape, Associate Engineer, Water Resources, was watermaster during this period.

The water supply for the 1967 irrigation season was well above average. Cold weather and late storms maintained a near record snowpack in the Warner Mountains until late in the spring. The extremely hot and dry summer, however, caused the flow of the smaller tributaries to fall off to only average amounts by late summer.

Pine Creek. Due to cold weather and the resulting low runoff, very close regulation was required during April and early May. Flow increased to over 100 percent of all allotments (2 priorities) by late May and remained fairly steady throughout June. Since the Modoc Refuge did not use its full allotment during some of this time, excess water was diverted for storage in Dorris Reservoir. As the flow decreased in the latter part of the season, those water users with more than one ditch followed their usual practice of rotating their allotments in

their various ditches. Flow had decreased to approximately 50 percent of first priority allotments by the end of the season.

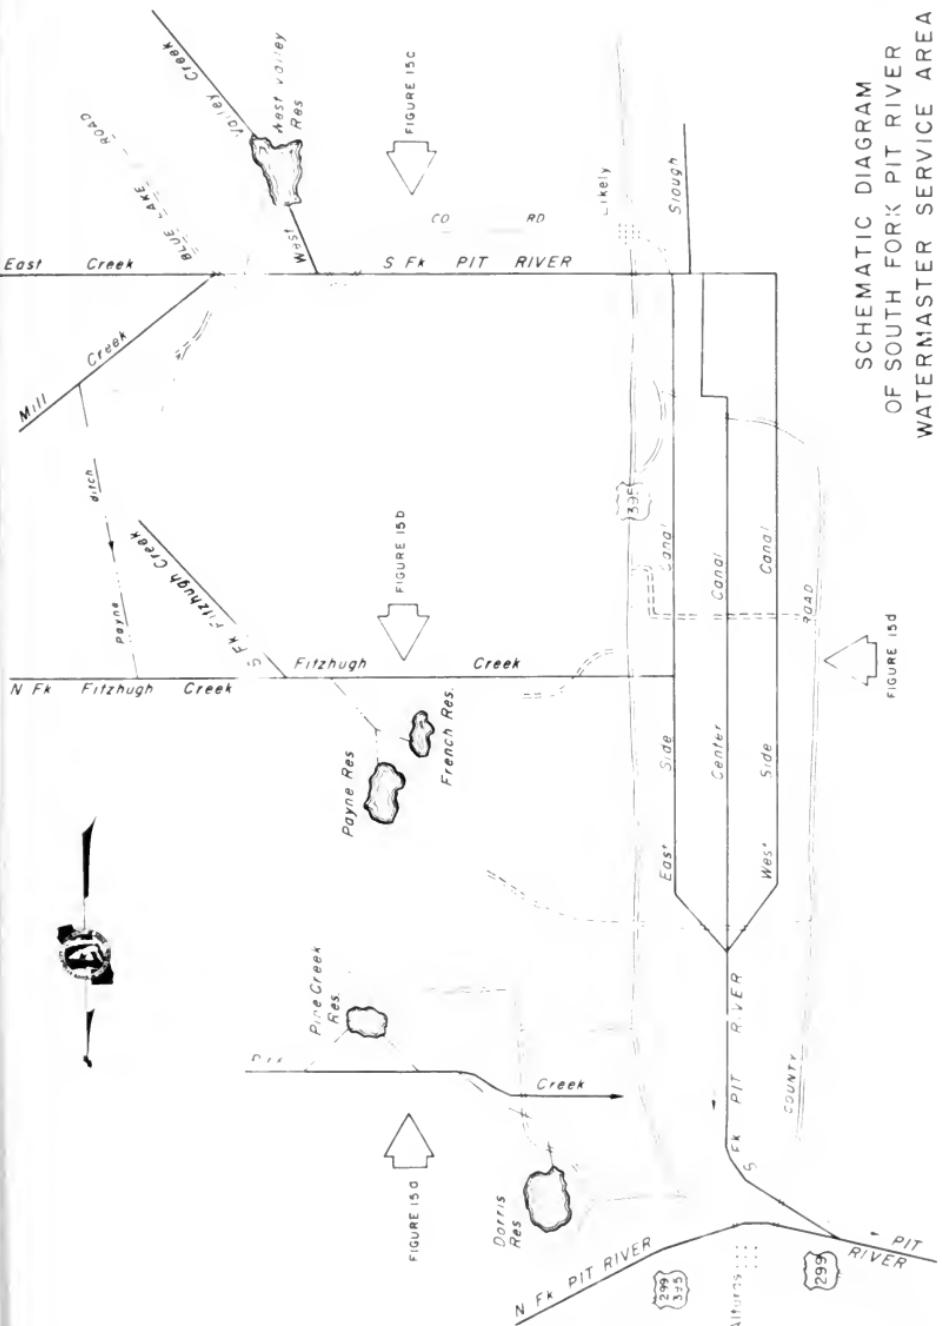

Fitzhugh Creek. Regulation began in late May when the Yankee Jim and Bowman Ditches became accessible. At that time there was more water than required to fill all allotments (2 priorities). The Payne Ditch from Mill Creek was opened on June 30. This additional water was added to the Bowman Ditch allotment. Flows gradually decreased from surplus to approximately 60 percent of first priority allotments at the end of the season.

South Fork Pit River. The natural flow of the South Fork Pit River was sufficient to meet all demands until July 14, at which time releases from West Valley Reservoir began.

Storage in the reservoir increased from 12,200 acre-feet at the beginning of the season, until its capacity of 22,240 acre-feet was reached on June 3. Water was released continuously from the reservoir for the rest of the season. At the end of September, 12,400 acre-feet remained in storage.

Surprise Valley Watermaster Service Area

The Surprise Valley service area is located in the extreme eastern part of Modoc County. There are 170 water right owners in the service area with total allotments of 313.75 cubic feet per second. The source of water supply is comprised of 10 individual stream systems rising on the eastern slope of the Warner Mountains. These streams are fed by snowmelt runoff and traverse a fast precipitous course down the eastern slope of the Warner Mountains to the valley floor. From that point, numerous, scattered diversion ditches convey water to the irrigated lands. The place of use is situated in a long, narrow area extending in a north-south direction between the foot of the Warner Mountains and the Alkali Lakes which lie in the center of Surprise Valley.

Surprise Valley extends from nearly the Oregon border on the north to Lassen County on the south, a distance of approximately 50 miles. The valley varies in width from about 8 to 10 miles. It is bordered on the north, south, and west by the rugged Warner Range and on the east by the typical mountainous desert terrain of Nevada. The valley floor is at an elevation of approximately 4,700 feet.

A schematic drawing of each major stream system within the Surprise Valley service area is presented as Figures 16 through 16j, pages 211 through 231.

Water Supply

The water supply is derived almost entirely from snowmelt runoff, with only minor spring-fed flows occurring in the latter part of the season. There are no known economically justified storage sites on the service area creeks. Because of the lack of regulatory storage, the available water supply at any specific diversion point may vary considerably within a few hours. An extreme differential in day and night temperatures causes extensive variation in snowmelt runoff quantities. This problem is further aggravated by the relatively

short and steep drainage area. In addition, occasional summer thunder showers may cause a creek to discharge a flow of mammoth portions for several hours. These flashes are apt to cause considerable damage in washouts and debris deposition, and are of such short duration that no beneficial use can be made of the water.

Records of the daily mean discharge at several stream gaging stations within the service area are presented in Tables 44 through 54, pages 233 through 243.

Method of Distribution

The continuous flow method of distribution is employed on most creeks; however, in a few instances the available water supply is rotated among the users in accordance with either decree schedules or by mutual agreements.

Alfalfa and meadow hay, the major crops grown in the valley, are irrigated in most instances by wild flooding. There are also considerable lands dependent upon subsurface irrigation. In addition, recent development of numerous deep wells has popularized sprinkler irrigation. This type of irrigation, however, is limited because of available ground water supply and costs of installation and maintenance.

To facilitate distribution of irrigation waters, construction of permanent diversion dams, headgates, and measuring devices has been stressed during recent years. Although these control devices do not solve the problems of discharge variation and debris deposition, they do provide significant assistance in solving water measurement and distribution problems.

The several decrees (see Table 1) which apply to the Surprise Valley service area establish the following number of priority classes for the various stream systems: Bidwell Creek - four until July 10, five thereafter; Mill Creek - four; Soldier Creek - rotation March 19 to June 19 (upper users eight, lower users seven), twelve priorities are in effect during the remainder of the year; Pine Creek - a rotation schedule based on accumulative flow in acre-feet is used; Cedar Creek - four; Deep Creek - five; Owl Creek - twenty-one; Rader Creek - six;

Eagle Creek - four; and Emerson Creek - four.

1967 Distribution

Watermaster service began March 19 in the Surprise Valley service area and continued until September 30. John A. Nolan, Water Resources Technician II, was watermaster during this period.

The 1967 irrigation season was very successful despite only average seasonal runoff in most streams, and considerably below average in a few whose headwaters are at relatively low elevations.

The snowpack on the Warner Mountains was well below normal at the beginning of the irrigation season. Frequent snowstorms and low temperatures during April and May, however, brought the snowpack to normal or above during the latter part of spring. Due to a fairly constant rate of snowmelt the runoff was sufficient to supply most allotments through the first half of the irrigation season. This produced an excellent yield for the first hay cuttings throughout the valley. Enough water remained in most creeks to begin irrigation for a second growth of hay. In most years only a few high priority water right owners can expect this additional water in July. However, the flows began to recede quickly during July, and by late September were essentially down to domestic and stockwater rights.

The seasonal runoff (April 1 through September 30) of the various streams ranged between 60 and 130 percent of the long-time averages.

Bidwell Creek. Total stream runoff available to Bidwell Creek users during the period from April 1 through September 30 was 15,560 acre-feet or approximately 130 percent of normal (based on records since 1955).

Due to a good snowpack in the Bidwell Creek basin there was enough runoff to supply all allotments until mid-June (four priorities until July 10, five priorities thereafter). From then until July 10 only third priority allotments were supplied. Bidwell Creek then receded at a fairly constant rate, reaching a low of approximately four cubic feet per second in late September. This was enough water to supply only first

priority allotments.

Mill Creek. Total stream runoff available to Mill Creek users during the period April 1 through September 30 was 5,550 acre-feet or approximately 100 percent of normal.

An abundant water supply existed throughout April, May, and most of June with much of the surplus flow wasting into Upper Alkali Lake. On June 29 the flow became insufficient to supply all allotments (four priorities). From then until late July, third priority water was available in steadily decreasing quantities. Second priority allotments were shut off in late August. Throughout the remainder of the season the available water supply was generally sufficient to satisfy the first priority allotments.

Soldier Creek. Total stream runoff available to Soldier Creek users during the period March 19 through September 30 was 2,130 acre-feet or approximately 60 percent of normal.

All diversions were closely regulated during the rotation periods (March 19 to June 19) as the water supply was inadequate to satisfy all allotments (eight priorities during the upper users' cycle, seven priorities during the lower users' cycle) until mid-May. At this time the stream runoff increased to provide surplus flows which lasted approximately ten days. In early June the flow began decreasing at a fairly constant rate. Partial second priority allotments were satisfied through early August. When the seasonal low was reached in late September, only partial first priority allotments were being served.

Pine Creek. Total stream runoff available to Pine Creek users during the period March 20 through September 30 was 1,410 acre-feet or approximately 100 percent of normal. The stream system was operated according to the rotation schedule (an accumulative flow basis) set forth by court decree.

On June 14 the flow dropped below four cubic feet per second, thereby ending the rotation schedule. The Alderman and Hutchens Ranches were then entitled to take all of the flow until it further receded to 1.6 cubic feet per second. This occurred on June 19. In accordance with the decree, the entire flow was then diverted into the Cressler Ditch to be used by the Bordwell Ranch. This diversion continued for about three

weeks, or as long as the water would reach the place of use. From mid-July until the end of the season Pine Creek was essentially dry.

Cedar Creek. Total stream runoff available to Cedar Creek users during the period April 1 through September 30 was about 2,410 acre-feet or approximately 80 percent of normal.

There was a sufficient water supply to satisfy all allotments (four priorities) until mid-May. Third priority allotments were satisfied through the end of May. Second priority regulation began during the first part of June as the streamflow continued to decline.

The entire flow was diverted to the only first priority water right owner from early July to the end of the season.

Deep Creek. Total stream runoff available to Deep Creek users during the period April 1 through September 30 was 2,420 acre-feet or approximately 65 percent of normal.

The water supply was sufficient to fulfill all third priority allotments (five priorities on the main stem of Deep Creek) until the third week in May. The streamflow then began to steadily recede. From this time until the end of the season the entire flow of North Fork Deep Creek was diverted into the Company Ditch, since only first priority water was available (one priority on North Deep Creek).

Second priority regulation began on the South Fork Deep Creek (two priorities) on June 1 and continued through June 10. Throughout the remainder of the irrigation season water was available for first priority allotments in steadily declining amounts.

Owl Creek. Total stream runoff available to Owl Creek users during the period April 1 through September 30 was 6,460 acre-feet, or approximately 100 percent of normal.

The flood control and distribution project is providing an excellent means of equitable distribution of irrigation waters. During the 1967 season the highest flow recorded in the system was 67 cubic feet per second, which is less than the design capacity of 75 cubic feet per second. The only distribution problem encountered was the usual one of gravel and debris accumulating at the intake, thereby restricting inflows to the system. A routine flushing schedule for the intake works was employed to minimize this problem.

Enough water existed to fulfill all of the 21 priorities until late June. For the remainder of the season the flow receded gradually, reaching a low of approximately one cubic foot per second in late September.

There was sufficient water available to supply all of the "special" eight priority allotments during their respective periods.

Rader Creek. Total stream runoff available to Rader Creek users during the period April 1 through September 30 was 3,190 acre-feet or approximately 95 percent of normal.

The water supply was sufficient to satisfy all allotments (six priorities) until the first of July. As the streamflow began receding, close regulation of all diversions was required to maintain equitable distribution. Diversion Number 1 was closed July 31, 1967, because not enough water was available to reach the place of use. The flow then receded steadily throughout the remainder of the irrigation season. Second priority allotments terminated on August 31 in accordance with the decree. During September, first priority water was available in varying amounts.

Eagle Creek. Total stream runoff available to Eagle Creek users during the period April 1 through September 30 was 3,940 acre-feet or approximately 65 percent of normal.

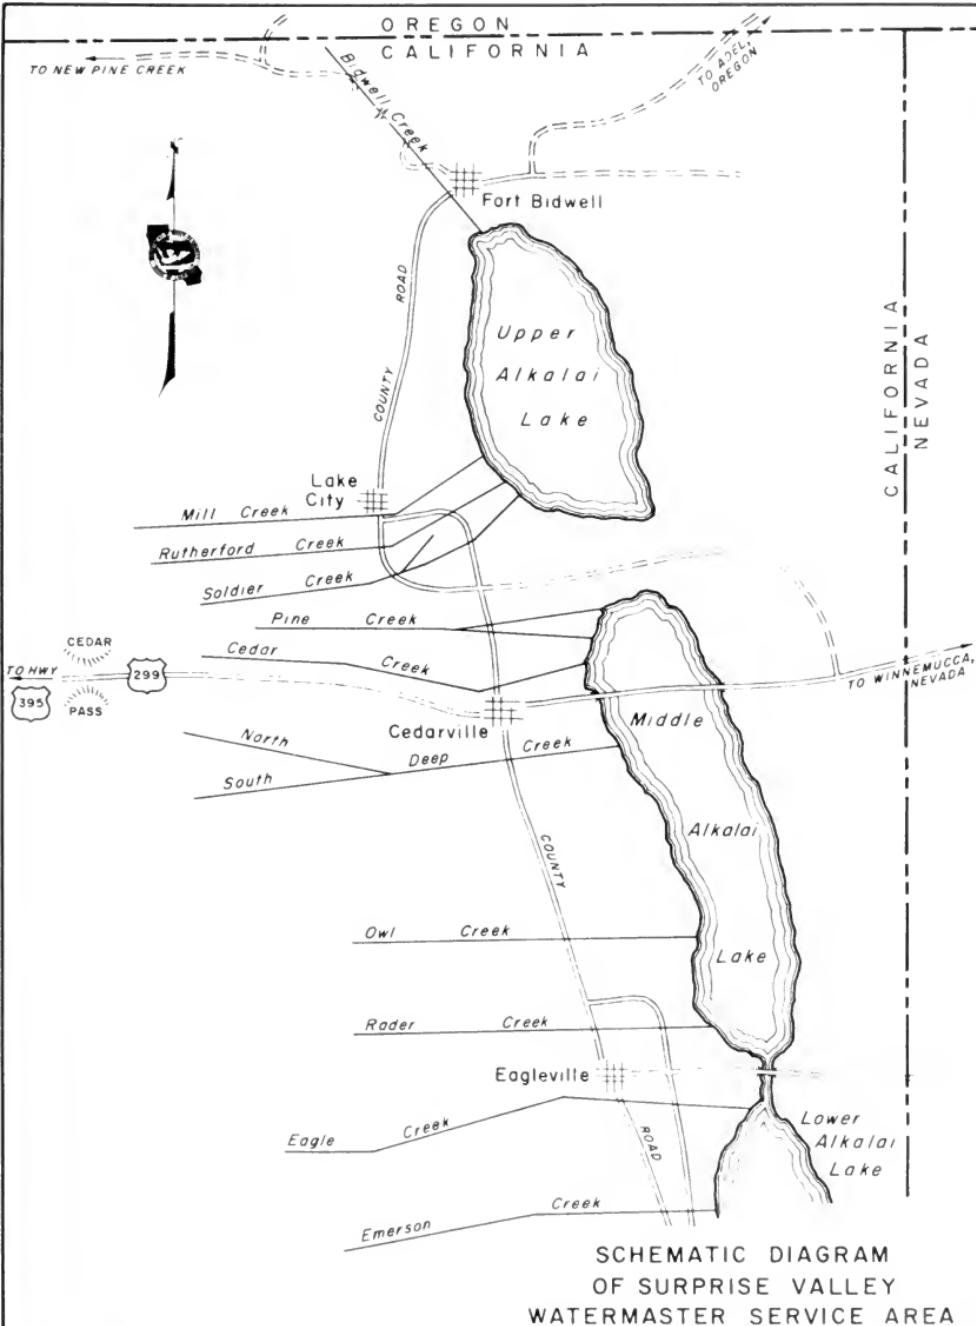

A sufficient water supply was available to satisfy all allotments (four priorities) until early July. Thereafter, the flow steadily receded. As the third priority supply decreased, excessive channel losses prevented any practical distribution in the lower reaches of the creek. In accordance with the decree, under these conditions the Ford Ranch was allowed to divert all third priority water. Second priority allotments were shut off in August. Thereafter, only first priority water was available (stockwater and domestic garden rights).

Emerson Creek. Total stream runoff available to Emerson Creek users during the period April 1 through September 30 was 3,120 acre-feet or approximately 85 percent of normal.

A sufficient water supply existed to satisfy all allotments (four priorities) until approximately the end of May. Fourth priority allotments were then terminated. Third priority allotments were shut

off on June 29 as the creek continued to recede. Throughout the remainder of the season second priority allotments were available in steadily decreasing amounts.

Emerson Creek users again supplemented their second growth irrigation supply by the use of several deep wells.

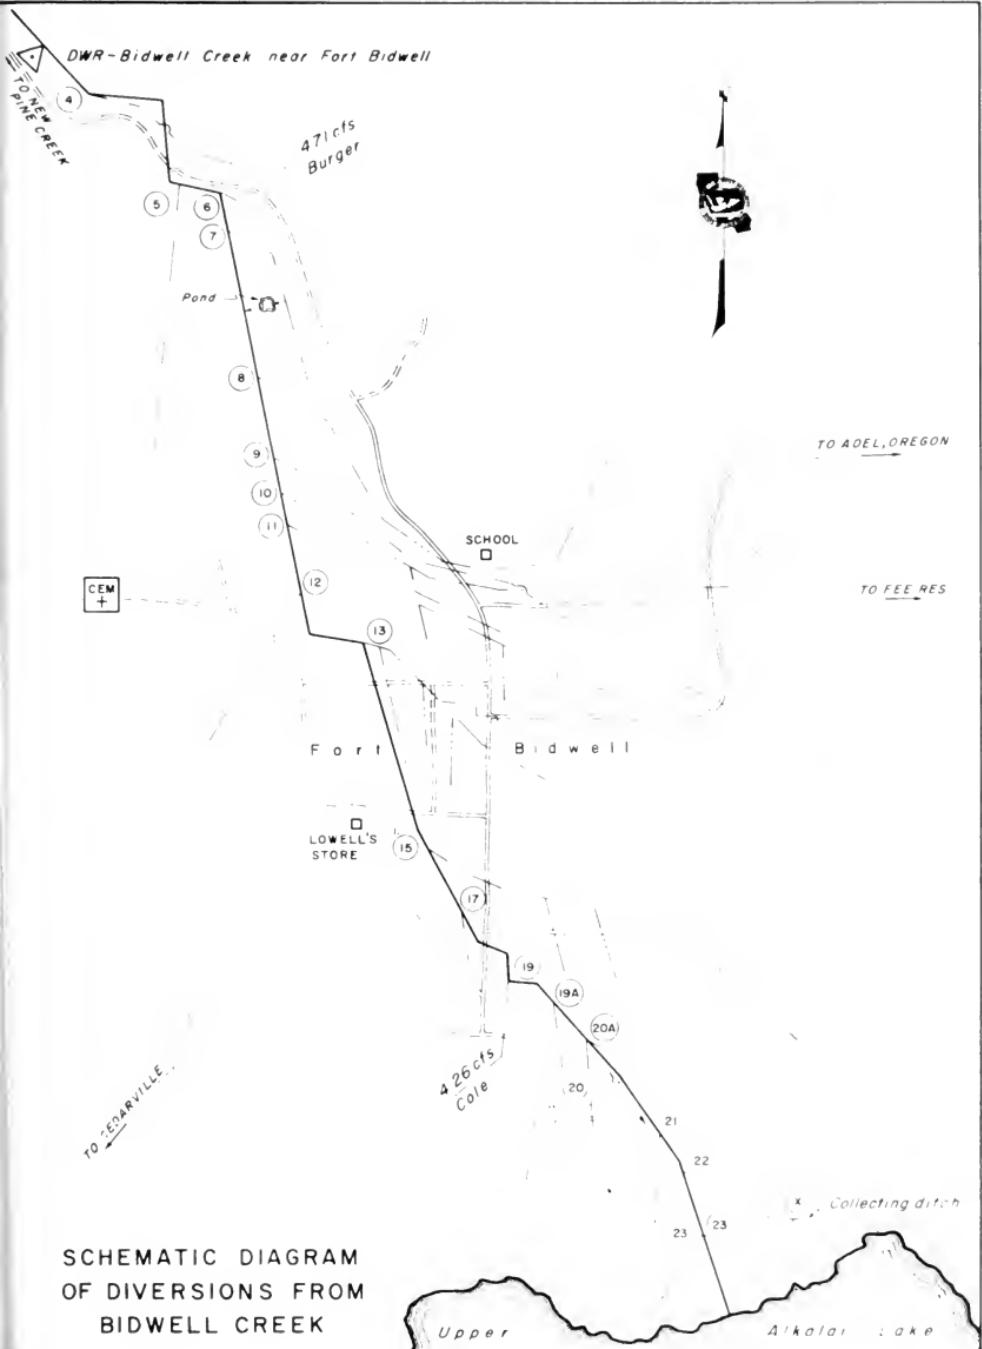

Permanent

Susan River Watermaster Service Area

The Susan River service area is located in the southern part of Lassen County in the vicinity of Susanville. There are 164 water right owners in the service area with total allotments of 351.732 cubic feet per second. The primary place of use is in Honey Lake Valley between Susanville and the northwest shore of Honey Lake, a distance of about 25 miles. The valley floor is at an elevation of about 4,000 feet. The source of supply is comprised of three stream systems: Susan River and tributaries, Baxter Creek and tributaries, and Parker Creek.

Susan River originates on the east slope of the Sierra Nevada immediately east of Lassen National Park at an elevation of about 7,900 feet. Its channel runs easterly from Silver Lake through McCoy Flat Reservoir, the town of Susanville, and then to Honey Lake.

Susan River has four major tributaries: Piute Creek, entering from the north at Susanville; Gold Run and Lassen Creeks, entering from the south between Susanville and Johnstonville; and Willow Creek, entering from the north above Standish. Gold Run and Lassen Creeks rise on the north slope of Diamond Mountain at an elevation of about 7,600 feet. The watersheds of Piute and Willow Creeks are on the south slopes of Round Valley Mountain at lower elevations.

A short distance below its confluence with Willow Creek the Susan River divides into three channels: Tanner Slough Channel on the north, Old Channel in the middle, and Dill Slough Channel on the south. Hartson Slough and Whitehead Slough divert from Dill Slough on its south bank farther downstream.

The Baxter Creek stream system is located in Honey Lake Valley on the east slope of the Sierra Nevada about 10 miles southeast of Susanville. The principal creeks in the system are: Baxter Creek, which rises in the extreme western portion of the basin and flows in an easterly direction; Elesian Creek, Sloss Creek, and Bankhead Creek are tributaries of Baxter Creek from the south.

Parker Creek is situated in Honey Lake Valley on the east slope of the Sierra Nevada about 15 miles southeast of Susanville. It rises on the east slope of Diamond Mountain and flows in a easterly direction for about five miles into Honey Lake.

A schematic drawing of each major stream system within the Susan River service area is presented as Figures 17 through 17e, pages 251 through 261.

Water Supply

The water supply in the Susan River service area is obtained from two major sources, snowmelt runoff and springs. Snowpack on the Willow Creek Valley and Piute Creek watersheds, which embrace more than one-half of the Susan River stream system, melts early in the spring and is usually depleted by May 1. Irrigation requirements from this portion of the stream system are then almost entirely dependent on the flow of springs that are relatively constant throughout the year.

Under average flow conditions, Lassen, Gold Run, Baxter, and Parker Creeks and Susan River above Susanville are sustained by snowmelt runoff until early June. The flow from perennial springs in this portion of the system is comparatively small.

The Lassen Irrigation District stores supplemental water in Hog Flat and McCoy Reservoirs, located on the headwaters of the Susan River. This stored water is released into the Susan River channel and commingled with the natural flow, usually during June and July. It is then rediverted into Lake Leavitt for further distribution by the irrigation district.

Records of the daily mean discharge of the several stream gaging stations in the service area are presented in Tables 55 through 63, pages 263 through 271.

Methods of Distribution

Irrigation in the Susan River service area is accomplished by placing dams in the main channels, thus raising the water level for subsequent diversion into canals and ditches. These diversion dams are

relatively large on the Susan River channel and much smaller on the tributaries. Wild flooding is the most common method of irrigation in practice. Portions of the irrigated lands have been leveled, permitting a more efficient use of water by using border checks and furrows. Subirrigation occurs in some areas incidental to surface irrigation or as a result of seepage from ditches and creek channels.

The Lassen Irrigation Company is entitled to divert or store up to the present capacity of its reservoirs from the natural flow of Susan River between March 1 and July 1 of each year when the flow of the Susan River immediately above Willow Creek is greater than 20 cubic feet per second. The company may divert at all other times when the flow of the Susan River immediately above Willow Creek is more than 5 cubic feet per second in spite of the allotments granted to users in Schedules 3 and 6 and to users of third priority class in Schedule 5 of the Susan River decree. When the flow of the Susan River immediately above Willow Creek is below the required amount the watermaster then measures the inflow to McCoy Flat Reservoir and if available, releases the amount required. A transportation loss of 15 percent, or a minimum of two cubic feet per second, is deducted from all water transferred from Lassen Irrigation Company upstream storage reservoirs, to Lake Leavitt.

The several decrees (see Table 1) which apply to the Susan River service area establish the following number of priority classes for the major stream systems and distribution areas: Baxter Creek - five; Parker Creek - four; Gold Run Creek - three; Lassen Creek - two; Piute and Hills Creek - one; Willow Creek - two; and Susan River - three. Geographical features are such that the Susan River, Willow Creek, and Lower Susan River areas are subject to interrelated priorities.

1967 Distribution

Watermaster service began March 27 in the Susan River service area and continued until September 30. Kenneth E. Morgan, Water Resources Engineering Associate, was watermaster during this period.

The available natural flow water supply throughout the Susan River

service area was well above average. An unusually heavy snowfall during April brought the May 1 snow survey measurements to about 200 percent of normal for the Susan River watershed. Many ranchers in the Honey Lake Valley reported record hay crop yields.

Parker Creek. The available water supply in Parker Creek was sufficient to satisfy all allotments (four priorities) until June 20. From June 20 to July 10 the flow decreased rapidly to first priority allotments. From July 10 throughout the remainder of the season only first priority allotments (stockwater) were served.

Baxter Creek. The available water supply in Baxter Creek was sufficient to supply all allotments (five priorities) until June 23. The flow rapidly decreased from June 25 to July 1 when approximately 50 percent of third priority allotments were supplied. From July 15 through September 30 the flow remained reasonably constant at approximately 50 percent of first priority allotments, providing some irrigation water for the upper users and stockwater for the lower users.

Lassen-Holtzclaw Creek. The available water supply in Lassen-Holtzclaw Creek was sufficient to meet all allotments (two priorities) until July 5. The flow decreased to first priority allotments on August 5. From August 5 throughout the remainder of the season the Tangeman Ranch was entitled to all of the water available in the stream system.

Hills Creek. The available water supply in Hills Creek was sufficient to supply all allotments (one priority) until about July 15. From August 1 through September 30 approximately 50 percent of the total allotments were served. All storage facilities on Hills Creek were filled during spring runoff.

Gold Run Creek. The available water supply in Gold Run Creek was sufficient to supply all allotments (three priorities) until July 5. From July 5 to August 1 the flow rapidly decreased to approximately 10 percent of second priority allotments. From August 1 through September 30 the flow remained reasonably constant at about 10 percent of second priority allotments.

Piute Creek. The available water supply in Piute Creek was sufficient to satisfy all allotments (one priority) and also provide a small surplus flow to the Susan River throughout the season.

Willow Creek. The available water supply in Willow Creek was sufficient to satisfy all allotments (two priorities) throughout the season.

A problem of heavy growth of moss, weeds, etc., exists annually in Willow Creek during the summer months. From July 5 through August 23, the Hansen and Nagata ranches in this area would not drain sufficiently for haying operations. Therefore, on July 26 a second pump was installed in Willow Creek at Horse Lake Road to assist in diverting water to the Eagle Lake Canal. This resulted in a lowering of the water surface in Willow Creek which allowed the moss and weeds to dry out and the low lands to drain.

Susan River. The available water supply in Susan River was sufficient to satisfy all allotments in Schedule 6 (three priorities) until June 23. As the flow receded Schedule 6 was terminated for the season. All allotments in Schedule 3 (two priorities - Lower Susan River area) were satisfied until July 5. From mid-July throughout the remainder of the season there was enough water for about 50 percent of second priority allotments in this schedule.

All allotments in Schedule 5 (three priorities - Upper Susan River area) were satisfied until July 4. From mid-July to August 15 there was enough water for about 25 percent of second priority allotments in this schedule. From August 15 throughout the remainder of the season, water was available for 10 percent of second priority allotments.

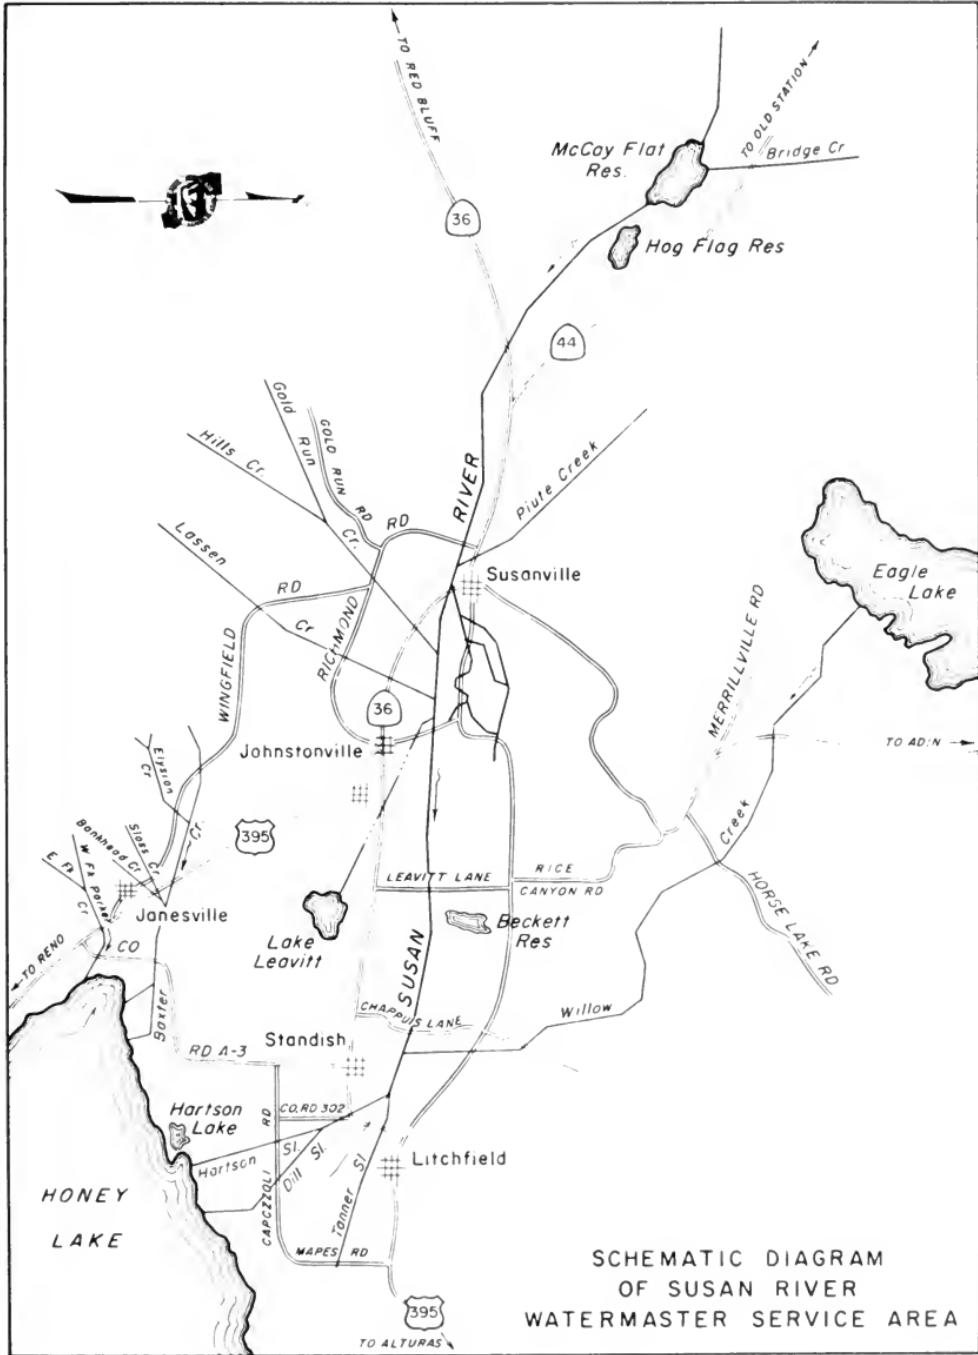

Lassen Irrigation Company Reservoirs. The Susan River decree allows the Lassen Irrigation Company's McCoy Flat and Lake Leavitt reservoirs to store surplus water during winter and spring months. Once filled, or if a shortage occurs among downstream water right owners, the natural flow in Susan River above McCoy Flat Reservoir must be released.

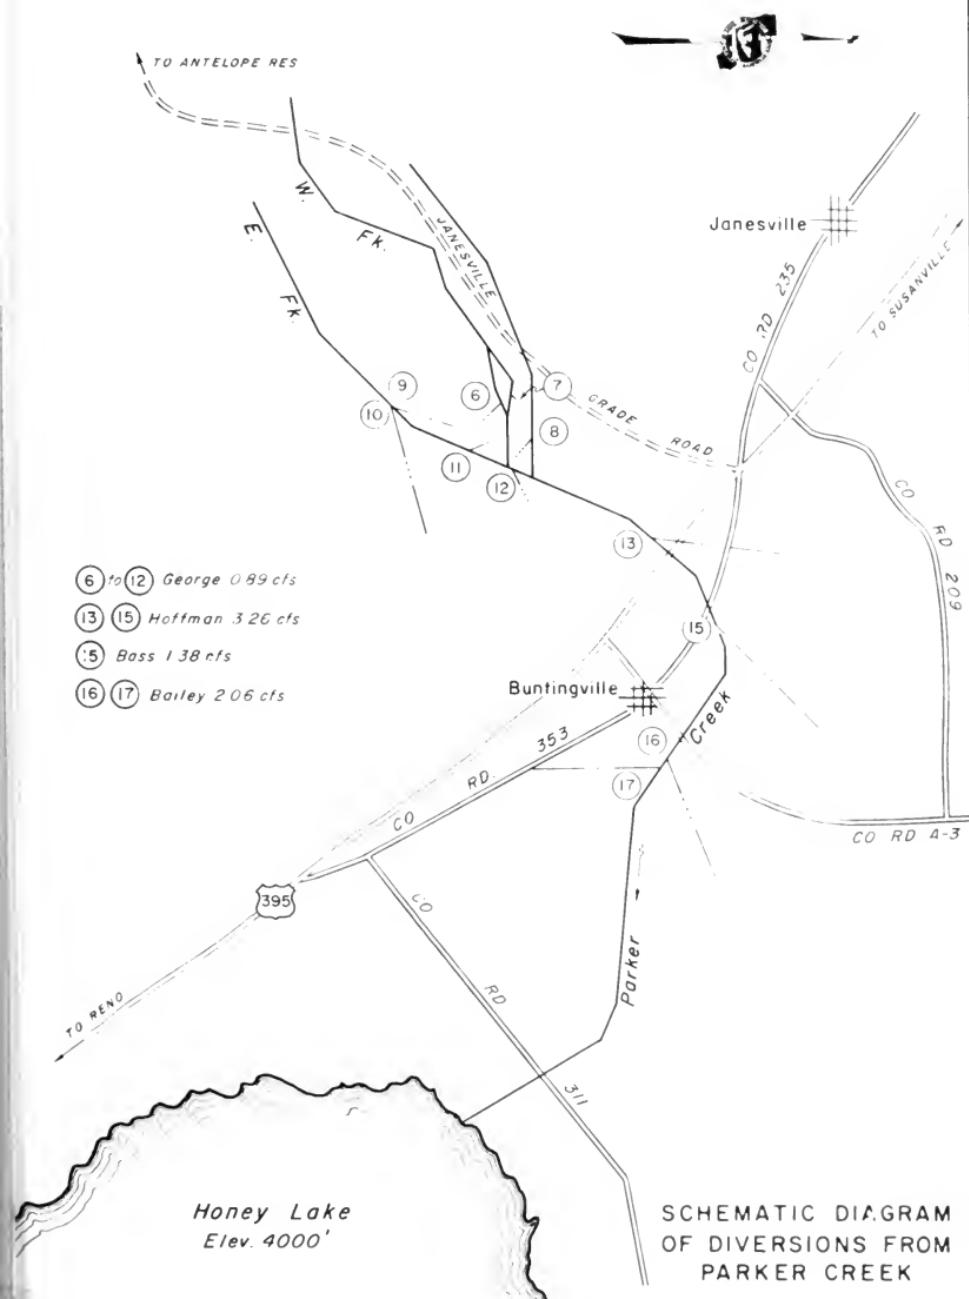

During early spring the above reservoirs fill'd to capacity. By July 4 the flow of Susan River became less than the evaporation losses in McCoy Flat Reservoir. Also, downstream water right owners were in need of additional water. Therefore, controlled releases had to be made. The Company requested that the required releases (equal to the inflow) from McCoy Flat Reservoir be made instead from their downstream Hog Flat Reservoir. This reservoir is quite shallow and has unusually high evaporation losses.

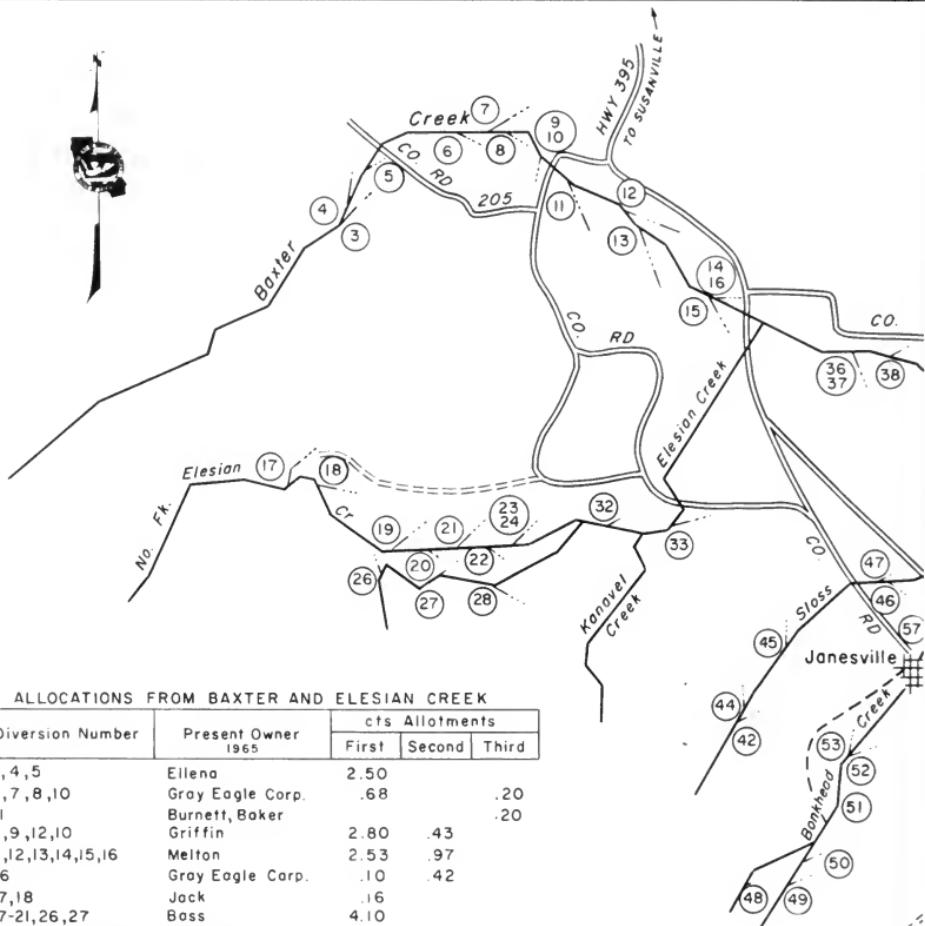

The watermaster granted permission to operate as requested. Consequently, between July 4 and July 14 at which time inflow to McCoy Flat Reservoir ceased for the summer, a total of 324 acre-feet was released from Hog Flat Reservoir for use by the downstream water right owners.

Special Occurrences

On July 20 an upright timber in the Lassen Irrigation Company diversion dam number 41 broke, sending approximately 130 cubic feet per second downstream. As a result the Barham Dam, diversion number 46 on the Susan River, was severely damaged. It was not in use for the remainder of the season. Water was again diverted into the diversion number 41 canal within nine hours after the break occurred.
